

General Description

The SLG47105 provides a small, low power component for commonly used Mixed-Signal and H-Bridge functions. The user creates their circuit design by programming the one time programmable (OTP) Non-Volatile Memory (NVM) to configure the interconnect logic, the IO Pins, the High Voltage Pins, and the macrocells of the SLG47105.

Configurable PWM macrocells in combination with Special High Voltage outputs will be useful for a motor drive or load drive applications. High Voltage pins allow to design smart level translators or to drive the high voltage high current load.

Key Features

- Two Power Supply Inputs:
 - 2.5 V ($\pm 8\%$) to 5.0 V ($\pm 10\%$) V_{DD}
 - 3.3 V ($\pm 10\%$) to 12.0 V ($\pm 10\%$) V_{DD2}
- Four High Voltage High Current Drive GPOs
 - Dual/Single H-Bridge Motor Driver Option
 - Quad/Dual/Single Half-Bridge Driver Option
 - Sleep Function
 - Low RDS ON High Side + Low Side resistance = 0.4 Ω
 - 2 A Peak, 1.5 A RMS per H-Bridge (at $V_{DD2} = 5\text{ V}$, $T = 25\text{ }^\circ\text{C}$) (**Note 1**)
 - 4 A Peak, 3 A RMS per two H-Bridge connected in parallel (at $V_{DD2} = 5\text{ V}$, $T = 25\text{ }^\circ\text{C}$) (**Note 1**)
 - 2 A Peak, 1.5 A RMS per Half Bridge GPO (at $V_{DD2} = 5\text{ V}$, $T = 25\text{ }^\circ\text{C}$) (**Note 1**)
- Integrated Protections:
 - Over Current Protection (OCP)
 - Short Circuit Protection (SCP)
 - Under-Voltage Lockout (UVLO)
 - Temperature Shutdown (TSD)
- SENSE_A, SENSE_B Inputs that are Connected to the Current Comparators for Current Control
- Fault Signal Indicator Individual per H-bridge:
 - OCP
 - UVLO
 - TSD
- Differential Amplifier with Integrator and Comparator for Motor Speed Control Function
- Two Current Sense Comparators with Dynamical Vref Mode
- Two High-Speed General Purpose ACMPs
 - Modes: UVLO, OCP, TSD, Voltage Monitor, Current Monitor
- One Voltage Reference (Vref) Output
- Five Multi-Function Macrocells
 - Four Selectable DFF/LATCH/3-bit LUTs + 8-bit Delay/Counters
 - One Selectable DFF/LATCH/4-bit LUT + 16-bit Delay/Counter
 - Twelve Combination Function Macrocells
 - Three Selectable DFF/LATCH or 2-bit LUTs
 - One Selectable Programmable Pattern Generator or 2-bit LUT
 - Six Selectable DFF/LATCH or 3-bit LUTs
 - One Selectable Pipe Delay or Ripple Counter or 3-bit LUT
 - One Selectable DFF/LATCH or 4-bit LUT
 - Two PWM Macrocells
 - Flexible 8-bit/7-bit PWM Mode with the Duty Cycle Control
 - 16 Preset Duty Cycle Registers Switching Mode for PWM Sine or Other Waveforms (**Note 2**)
 - Serial Communications
 - I²C Protocol Interface
 - Programmable Delay with Edge Detector Output
 - Additional Logic Function – One Deglitch Filter with Edge Detectors
 - Two Oscillators (OSC)
 - 2.048 kHz Oscillator
 - 25 MHz Oscillator
 - Analog Temperature Sensor with ACMP Connected Output
 - POR
 - One Time Programmable Memory
 - Operating Temperature Range: $-40\text{ }^\circ\text{C}$ to $85\text{ }^\circ\text{C}$
 - RoHS Compliant/Halogen-Free
 - 20-pin STQFN: 2 mm x 3 mm x 0.55 mm, 0.4 mm pitch

Applications

- Smart Locks
- Personal Computers and Servers
- Consumer Electronics
- Motor Drivers
- Toys
- HV MOSFET Drivers
- Video Security Cameras
- LED Matrix Dimmers

Note 1 Power dissipation and thermal limits must be observed. See Section 3.3

Note 2 For all PWM features see Section 13.

2 Pinout

2.1 PIN CONFIGURATION - STQFN- 20L

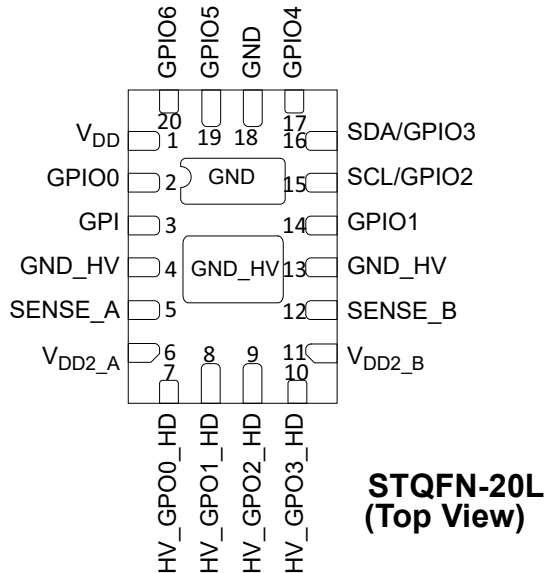

Table 1: Pin Description

Pin #	Signal Name	Pin Functions
1	V _{DD}	Power Supply 2.5 V – 5.0 V
2	GPIO0	Matrix OE GPIO, Vref OUT, Diff Amp Vset Input, TS_OUT
3	GPI	GPI, EXT_Vref0, SLA_0
4	GND_HV	Analog Ground
5	SENSE_A	Winding A Sense, relate to HV_GPO0_HD, HV_GPO1_HD
6	V _{DD2_A}	High Voltage Power Supply 3.3 V - 12.0 V (Note)
7	HV_GPO0_HD	HV_GPO_HD
8	HV_GPO1_HD	HV_GPO_HD
9	HV_GPO2_HD	HV_GPO_HD
10	HV_GPO3_HD	HV_GPO_HD
11	V _{DD2_B}	High Voltage Power Supply 3.3 V - 12.0 V (Note)
12	SENSE_B	Winding B Sense, relate to HV_GPO2_HD, HV_GPO3_HD
13	GND_HV	Analog Ground
14	GPIO1	Matrix OE GPIO, SLA_1, EXT_CLK for OSC0 or Current Sense CMP0 EXT_Vref
15	SCL/GPIO2	SCL, GPIO
16	SDA/GPIO3	SDA, GPIO
17	GPIO4	Matrix OE GPIO, EXT_Vref1, SLA_2, EXT_CLK for OSC1 or Current Sense CMP1 EXT_Vref
18	GND	General Ground
19	GPIO5	Matrix OE GPIO, ACMP0_H
20	GPIO6	Matrix OE GPIO, SLA_3, ACMP1_H

Legend:

- ACMP:** Analog Comparator
- CMP:** Comparator
- Diff Amp:** Differential Amplifier
- GPI:** General Purpose Input
- GPO:** General Purpose Output
- GPIO:** General Purpose Input/Output
- HD:** High Current Drive
- HV:** High Voltage
- SCL:** I²C Clock Input
- SDA:** I²C Data Input/Output
- SLA_x:** Slave Address
- Vrefx:** Voltage Reference Output
- TP:** Thermal Pad
- TS_OUT:** Temperature Sensor Output
- EXT:** External
- CLK:** Clock

Table 2: Pin Type Definitions

Pin Type	Description
V _{DD}	Power Supply
GPIO	General Purpose Input/Output
GPI	General Purpose Input
HV_GPO_HD	High Voltage General Purpose Output High Current Drive
SCL	I ² C Serial Clock Input
SDA	I ² C Serial Data Input/Output
GND	General Ground
GND_X	Analog Ground
SENSE_X	Current Sense Pin
V _{DD2}	High Voltage Power Supply

3 Characteristics

3.1 ABSOLUTE MAXIMUM RATINGS

Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, so functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specification are not implied. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability.

Table 3: Absolute Maximum Ratings

Parameter	Description	Condition	Min	Max	Unit
Supply voltage on V_{DD} relative to GND			-0.3	7.0	V
Voltage at V_{DD} Group Input Pin			-0.3	7.0	V
Supply voltage on V_{DD2} relative to GND pin			-0.3	18	V
Maximum V_{DD} Average or DC Current	(Through V_{DD} or GND pin) for V_{DD} group for STQFN-20L Package		--	120	mA
Maximum V_{DD2} Average or DC Current	(Through V_{DD2_A} , V_{DD2_B} , SENSE_A or SENSE_B pin) STQFN-20L Package	All HV GPOs are in H-Bridge mode	--	2000	mA
	(Through both V_{DD2_A} and V_{DD2_B} pins or both SENSE_A and SENSE_B pins) STQFN-20L Package		--	4000	
Maximum Average or DC Current (V_{DD2} power supply)	Push-Pull	Through V_{DD2} High Current Group pins	--	1500	mA
Maximum pulsed current sink/sourced per HV HD pin		Pulse width ≤ 0.5 ms; duty cycle ≤ 2 %	--	Internally limited by OCP	mA
Current at Input Pin		Through V_{DD} Group pin	-0.1	1.0	mA
Input Leakage Current (Absolute Value)			--	1000	nA
Storage Temperature Range			-65	150	$^{\circ}$ C
Junction Temperature			--	150	$^{\circ}$ C
Moisture Sensitivity Level				1	

3.2 ELECTROSTATIC DISCHARGE RATINGS

Table 4: Electrostatic Discharge Ratings

Parameter	Min	Max	Unit
ESD Protection (Human Body Model)	4000	--	V
ESD Protection (Charged Device Model)	1300	--	V

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

3.3 RECOMMENDED OPERATING CONDITIONS

Table 5: Recommended Operating Conditions

Parameter	Condition	Min	Typ	Max	Unit
Supply Voltage (V_{DD})		2.3	3.3	5.5	V
High Supply Voltage (V_{DD2})		3.0	12.0	13.2	V
Operating Ambient Temperature (T_A)		-40	25	85	°C
Junction Temperature Range (T_J)	(Note)	-40	--	150	°C
Capacitor Value at V_{DD}			0.1	--	μF
Analog Input Common Mode Range	Allowable Input Voltage at Analog Pins	0	--	V_{DD} or V_{DD2} (Note 1)	V

Note 1 V_{DD} for GPI, GPIO4, GPIO5, GPIO6 and V_{DD2} for HV GPO0 and HV GPO1

3.4 THERMAL INFORMATION

Table 6: Recommended Operating Conditions

Parameter	Description	Condition	Min	Max	Unit
θ_{JA}	Thermal Resistance	4L JEDEC PCB	--	65	°C/W
θ_{JA}	Thermal Resistance	4L JEDEC PCB with a thermal vias that connect thermal pad through all layers of the PCB	--	46	°C/W

3.5 ELECTRICAL CHARACTERISTICS

Table 7: EC at $T = -40\text{ °C}$ to $+85\text{ °C}$, $V_{DD} = 2.3\text{ V}$ to 5.5 V Unless Otherwise Noted

Parameter	Description	Condition	Min	Typ	Max	Unit
V_{IH}	HIGH-Level Input Voltage for V_{DD} group	Logic Input (Note 1)	$0.7 \times V_{DD}$	--	$V_{DD} + 0.3$	V
		Logic Input with Schmitt Trigger	$0.8 \times V_{DD}$	--	$V_{DD} + 0.3$	V
		Low-Level Logic Input (Note 1)	1.25	--	$V_{DD} + 0.3$	V
V_{IL}	LOW-Level Input Voltage for V_{DD} group	Logic Input (Note 1)	GND-0.3	--	$0.3 \times V_{DD}$	V
		Logic Input with Schmitt Trigger	GND-0.3	--	$0.2 \times V_{DD}$	V
		Low-Level Logic Input (Note 1)	GND-0.3	--	0.5	V

Table 10: HV Output Electrical Characteristic (H-Bridge or Half-Bridge Modes)(Continued)

Parameter	Description	Condition	Min	Typ	Max	Unit
I_{OFF}	Off-state leakage current	GPO0_HD, GPO1_HD, $V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }85\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	0	--	29.9	μA
		GPO0_HD, GPO1_HD, $V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	-0.2	--	32.2	μA
		GPO2_HD, GPO3_HD, $V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }85\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	-3.9	--	5.7	nA
		GPO2_HD, GPO3_HD, $V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	-0.3	--	0.6	μA
I_{CC}	Charge Pump consumption current	$V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	--	160	200	μA
		$V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$ PWM = 250 kHz	100	--	600	μA
t_{WAKE}	Wake-up time	HV SLEEP OUT high to output transition, BG is always on, Another pins sleep - disable	--	33	100	μs

Table 11: HV Output Electrical Characteristic (Pre-driver Mode)

Parameter	Description	Conditions	Min	Typ	Max	Unit
t_R	Rise time HV OUT	$V_{DD2} = 5\text{ V}$, 16 Ω to GND, 10 % to 90 % V_{DD2} , $T_J = -40\text{ }^\circ\text{C to }85\text{ }^\circ\text{C}$	--	18	--	ns
		$V_{DD2} = 5\text{ V}$, 16 Ω to GND, 10 % to 90 % V_{DD2} , $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$	--	18	--	ns
t_F	Fall time HV OUT	$V_{DD2} = 5\text{ V}$, 16 Ω to GND, 10 % to 90 % V_{DD2} , $T_J = -40\text{ }^\circ\text{C to }85\text{ }^\circ\text{C}$	--	18	--	ns
		$V_{DD2} = 5\text{ V}$, 16 Ω to GND, 10 % to 90 % V_{DD2} , $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$	--	18	--	ns

Table 11: HV Output Electrical Characteristic (Pre-driver Mode) (Continued)

Parameter	Description	Conditions	Min	Typ	Max	Unit
t_{DEAD}	Dead band time of HV_GPOx_HD in Pre-driver mode (not for Driver mode) (Break before making For H-bridge and Half-Bridge mode)	$V_{DD2} = 3\text{ V}$, $T_J = -40\text{ °C}$ to 150 °C	--	55	--	ns
		$V_{DD2} = 5\text{ V}$, $T_J = -40\text{ °C}$ to 150 °C	--	25	--	ns
		$V_{DD2} = 13.2\text{ V}$, $T_J = -40\text{ °C}$ to 150 °C	--	23	--	ns
PWM_ t_{DEAD}	PWM dead band time	Configured in PWM block	0; $1 \cdot T_{clk}$; $2 \cdot T_{clk}$; $3 \cdot T_{clk}$;			Clk time
$R_{DS(ON)}$	HS FET on resistance (SENSE_A, SENSE_B, GND_HV and GND Pins are connected together)	$V_{DD2} = 13.2\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 25\text{ °C}$	--	169.8	--	m Ω
		$V_{DD2} = 13.2\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 150\text{ °C}$	--	--	328.4	m Ω
		$V_{DD2} = 9.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 25\text{ °C}$	--	169.9	--	m Ω
		$V_{DD2} = 9.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 150\text{ °C}$	--	--	327.9	m Ω
		$V_{DD2} = 5.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 25\text{ °C}$	--	175.3	--	m Ω
		$V_{DD2} = 5.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 150\text{ °C}$	--	--	335.5	m Ω
		$V_{DD2} = 3.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 25\text{ °C}$	--	246.2	--	m Ω
		$V_{DD2} = 3.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 150\text{ °C}$	--	--	454.5	m Ω
	LS FET on resistance (SENSE_A, SENSE_B, GND_HV and GND Pins are connected together)	$V_{DD2} = 13.2\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 25\text{ °C}$	--	181.9	--	m Ω
		$V_{DD2} = 13.2\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 150\text{ °C}$	--	--	355.7	m Ω
		$V_{DD2} = 9.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 25\text{ °C}$	--	181.9	--	m Ω
		$V_{DD2} = 9.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 150\text{ °C}$	--	--	354.9	m Ω
		$V_{DD2} = 5.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 25\text{ °C}$	--	185.2	--	m Ω
		$V_{DD2} = 5.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 150\text{ °C}$	--	--	362.7	m Ω
		$V_{DD2} = 3.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 25\text{ °C}$	--	228.6	--	m Ω
		$V_{DD2} = 3.0\text{ V}$, $I_o = 500\text{ mA}$, $T_J = 150\text{ °C}$	--	--	449.9	m Ω

Table 11: HV Output Electrical Characteristic (Pre-driver Mode) (Continued)

Parameter	Description	Conditions	Min	Typ	Max	Unit
I_{OFF}	Off-state leakage current	GPO0_HD, GPO1_HD, $V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }85\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	0	--	29.9	μA
		GPO0_HD, GPO1_HD, $V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	-0.2	--	32.2	μA
		GPO2_HD, GPO3_HD, $V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }85\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	-3.9	--	5.7	nA
		GPO2_HD, GPO3_HD, $V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$ PWM is off, including the charge pump OSC	-0.3	--	0.6	μA
I_{CC}	Charge Pump consumption current	$V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$, PWM is off, including the charge pump OSC	--	160	200	μA
		$V_{DD2} = 5.0\text{ V}$, $T_J = -40\text{ }^\circ\text{C to }150\text{ }^\circ\text{C}$, PWM = 250 kHz	100	--	600	μA
t_{WAKE}	Wake-up time	HV SLEEP OUT high to output transition, BG is always on, Another pins sleep - disable	--	33	100	μs

3.7 PROTECTION CIRCUITS ELECTRICAL CHARACTERISTIC

Table 12: Protection Circuits

Parameter	Description	Conditions	Min	Typ	Max	Unit
I_{OCP}	Overcurrent protection threshold	Per any HS or LS FET	--	2.2	--	A
t_{OCP1}	OCP deglitch time (Note 1)	$V_{DD} = 5\text{ V}$, $V_{DD2} = 5\text{ V}$, $T = 25\text{ }^\circ\text{C}$, Deglitch = Enable, High Side	--	2	--	μs
		$V_{DD} = 5\text{ V}$, $V_{DD2} = 5\text{ V}$, $T = 25\text{ }^\circ\text{C}$, Deglitch = Enable, Low Side	--	2	--	μs

Table 12: Protection Circuits

Parameter	Description	Conditions	Min	Typ	Max	Unit
t_{OCP2}	OCP retry time (Note 2)	Delay = 492 μs	--	492	--	μs
		Delay = 656 μs	--	656	--	μs
		Delay = 824 μs	--	824	--	μs
		Delay = 988 μs	--	988	--	μs
		Delay = 1152 μs	--	1152	--	μs
		Delay = 1316 μs	--	1316	--	μs
		Delay = 1480 μs	--	1480	--	μs
		Delay = 1640 μs	--	1640	--	μs
V_{UVLO}	Recover from undervoltage lockout	At rising edge of V_{DD2}	--	--	3.0	V
	Undervoltage lockout	At falling edge of V_{DD2}	--	--	2.8	V
T_{TSD}	Thermal shutdown temperature	Junction temperature T_{J}	140	150	160	$^{\circ}\text{C}$
T_{HYST}	Thermal shutdown hysteresis		--	15	--	$^{\circ}\text{C}$

Note 1: OCP deglitch time option can be enabled by register [873] and register [875] separately for each H-Bridge.

Note 2: OCP retry time can be selected separately for each HV OUT: HV GPO0 - registers[780:778], HV GPO1 - registers[788:786], HV GPO2 - registers[796:794], HV GPO3 - registers[804:802]. For more information check the Section 7.5.3.

3.8 TIMING CHARACTERISTICS

Table 13: Typical Startup Estimated for Chip at $T = 25^{\circ}\text{C}$

Parameter	Description	Conditions	Min	Typ	Max	Unit
T_{SU}	Chip Startup Time	From V_{DD} rising past PON_{THR}	--	1	2	ms

Table 14: Typical Delay Estimated for Each Macrocell at $T = 25^{\circ}\text{C}$

Parameter	Description	Note	$V_{\text{DD}} = 2.5\text{ V}$		$V_{\text{DD}} = 3.3\text{ V}$		$V_{\text{DD}} = 5\text{ V}$		Unit
			Rising	Falling	Rising	Falling	Rising	Falling

4 User Programmability

The SLG47105 is a user programmable device with one time programmable (OTP) memory elements that are able to configure the connection matrix and macrocells. A programming development kit allows the user the ability to create initial devices. Once the design is finalized, the programming code (.gpx file) is forwarded to Dialog Semiconductor to integrate into a production process.

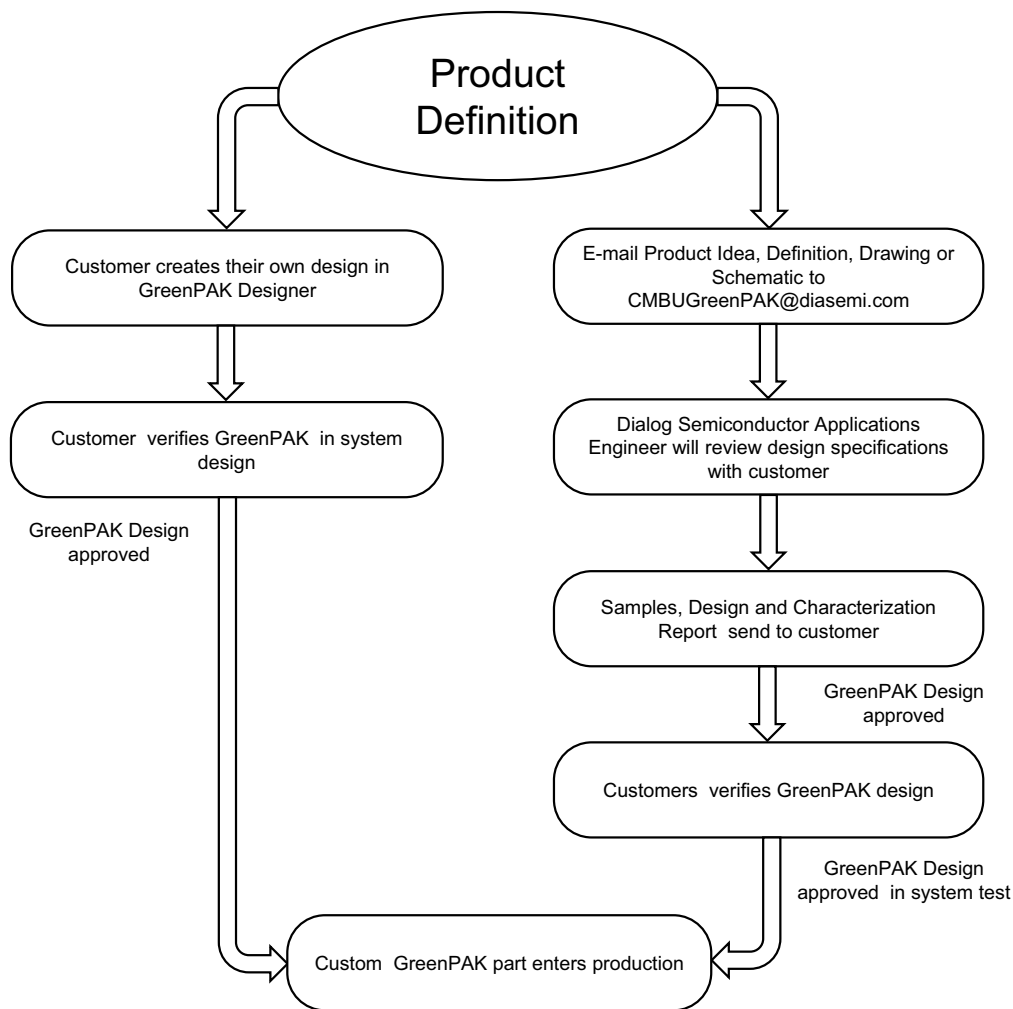

Figure 2: Steps to Create a Custom GreenPAK Device

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

5 System Overview

5.1 GPIO PINS

- Digital Input (low voltage or normal voltage, with or without Schmitt Trigger)
- NMOS Open-Drain Outputs
- Push-Pull Outputs
- Analog IO
- 10 k Ω /100 k Ω /1 M Ω Pull-up/Pull-down resistors
- GPIO with OE can be configured as bidirectional IO or three-state output

5.2 HIGH VOLTAGE OUTPUT PINS

- High voltage digital output in Push-Pull, Open-Drain configurations or H-Bridge logic
- Build-in Overcurrent and Short Circuit protection
- Configurable Dead Band Time
- Sleep mode to save energy
- Advanced Voltage Control and Current Control

5.3 CONNECTION MATRIX

- Digital matrix for circuit connections based on user design

5.4 TWO CURRENT SENSE COMPARATORS

- SENSE_x pin connected input for Advanced Current Control
- Separate Selectable Vref: 6-bit selection
- Static or Dynamic Vref selection
- Configurable Gain: 4x or 8x

5.5 DIFFERENTIAL AMPLIFIER WITH INTEGRATOR AND COMPARATOR

- Low Quiescent Current
- Provide constant motor speed for variable V_{DD2}
- Connected to HV GPO0 and HV GPO1

5.6 TWO GENERAL PURPOSE ANALOG COMPARATORS

- Wide Vref Selector: 32 mV to 2016 mV, with 32 mV step
- Selectable hysteresis: 2-bit selection
- Configurable Gain (resistor divider) 1x; 0.5x; 0.33x; 0.25x
- Different input sources: PINS, V_{DD} or Temp sense

5.7 VOLTAGE REFERENCE

- Used for references on Analog Comparators
- Can be driven to external pin

5.8 TWELVE COMBINATION FUNCTION MACROCELLS

- Three Selectable DFF/LATCH or 2-bit LUTs
- One Selectable Programmable Pattern Generator or 2-bit LUT
- Six Selectable DFF/LATCH with Set/Reset input or 3-bit LUTs
- One Selectable Pipe Delay or Ripple Counter or 3-bit LUT
- One Selectable DFF/LATCH with Set/Reset input or 4-bit LUT

5.9 FIVE MULTI-FUNCTION MACROCELLS

- Four Selectable DFF/LATCH/3-bit LUTs + 8-bit Delay/Counters
- One Selectable DFF/LATCH/4-bit LUT + 16-bit Delay/Counter

5.10 TWO PWM MACROCELLS

- Flexible 8-bit or 7-bit PWM mode with the Duty Cycle control
- True 0 % and 100 % Duty Cycle
- Regular or 16 Preset Registers mode
- Autostop mode
- Phase correct mode
- Selectable separate Dead Band Time

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

- Glitch Safety

5.11 SERIAL COMMUNICATION

- I²C Interface

5.12 PROGRAMMABLE DELAY

- 125 ns/250 ns/375 ns/500 ns @ 3.3 V
- Includes Edge Detection function

5.13 ADDITIONAL LOGIC FUNCTION

- One Deglitch filter macrocell
- Includes Edge Detection function

5.14 TWO OSCILLATORS

- 2.048 kHz
- 25 MHz

5.15 DUAL V_{DD}

- General Power Supply V_{DD} in range 2.5 V to 5.0 V
- Second Power Supply V_{DD2} in range 3.3 V to 12.0 V (**Note**)
- Two GPIOs groups: V_{DD} GPIOs Group, V_{DD2} GPOs Group

Note V_{DD2_A} Pin should be used necessarily if V_{DD2} is used. Using V_{DD2_B} without using V_{DD2_A} is unacceptable, because internal high voltage circuit part is supplied by V_{DD2_A} Pin. Therefore, HV_GPO0_HD and HV_GPO1_HD should be used firstly.

6 Input/Output Pins

6.1 GPIO PINS

The SLG47105 has a total of 7 GPIO, 1 GPI, and 4 HV GPO Pins, which can function as either a user-defined Input or Output, as well as serving as a special function (such as outputting the voltage reference).

6.2 GPI PIN

GPI serves as General Purpose Input Pin of V_{DD} Group.

6.3 HV GPO PINS

HV GPO0, HV GPO1, HV GPO2, HV GPO3 serve as High Voltage General Purpose Output Pins of V_{DD2} Group.

6.4 PULL-UP/DOWN RESISTORS

All IO Pins of V_{DD} Group have the option for user selectable resistors connected to the input structure. The selectable values on these resistors are 10 k Ω , 100 k Ω , and 1 M Ω . The internal resistors can be configured as either Pull-up or Pull-downs.

6.5 FAST PULL-UP/DOWN DURING POWER-UP

During power-up, IO Pull-up/down resistance will switch to 2.6 k Ω initially and then it will switch to the normal setting value. This function is enabled by register [754].

6.6 GPI IO STRUCTURE (FOR V_{DD} GROUP)

6.6.1 GPI IO Structure

Input Mode [1:0]
 00: Digital In without Schmitt Trigger, wosmt_en = 1
 01: Digital In with Schmitt Trigger, smt_en = 1
 10: Low Voltage Digital In mode, lv_en = 1
 11: Analog IO mode

Note: Can be varied over PVT, for reference only.

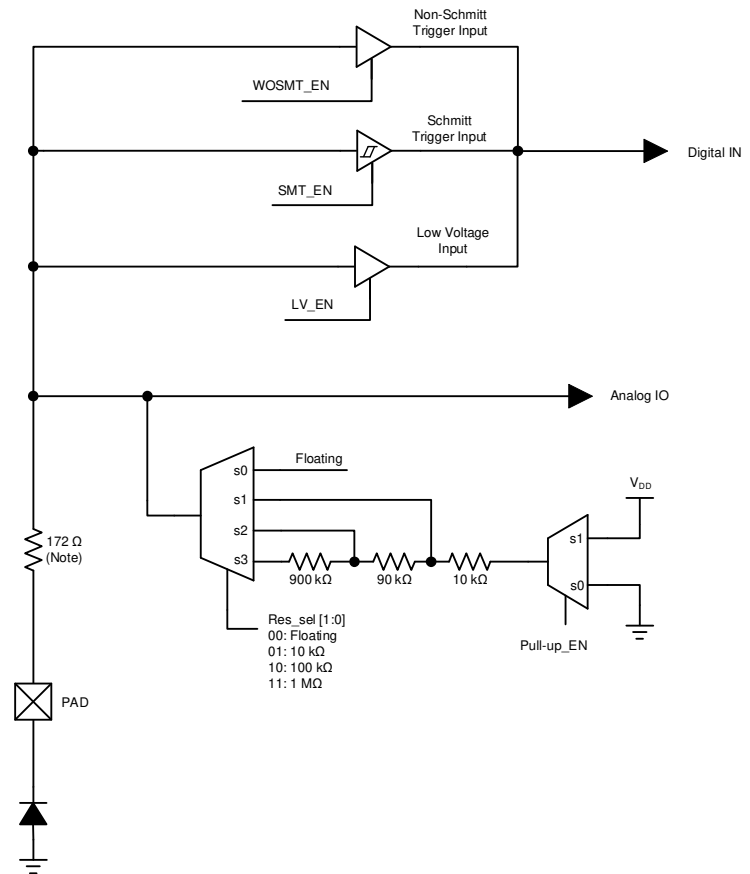

Figure 3: GPI Structure Diagram

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

6.7 I²C MODE IO STRUCTURE (FOR V_{DD} GROUP)

6.7.1 I²C Mode IO Structure (for SCL/GPIO2 and SDA/GPIO3, Register OE)

Input Mode [1:0]
 00: Digital Input without Schmitt Trigger, WOSMT_EN = 1
 01: Digital Input with Schmitt Trigger, SMT_EN = 1
 10: Low Voltage, Digital Input, LV_EN = 1
 11: Reserved

- Note 1:** It is possible to apply an input voltage higher than V_{DD} to GPIO2 and GPIO3. However, this voltage should not exceed 5.5 V
- Note 2:** GPIO2 and GPIO3 don't support Push-Pull and PMOS Open-Drain modes
- Note 3:** When an internal Pull-up/down is used, the input voltage can't be higher than V_{DD}
- Note 4:** OE goes HIGH only when I²C_EN signal = 0 and register [831] = 1 (for GPIO2)/register[837] = 1 (for GPIO3)
- Note 5:** When QE is HIGH, Input Mode[1:0] = 11 must be selected
- Note 6:** When I²C_EN signal = 1, fast+ mode (3.2x OD for SDA) can be selected by register [830] = 0 and standard/fast mode (0.8x OD for SDA) can be selected by register [830] = 1
- Note 7:** When QE is HIGH, only OD 3.2x option is active
- Note 8:** When I²C_EN signal = 1, internal Pull-Up/Down Resistors would be always floating

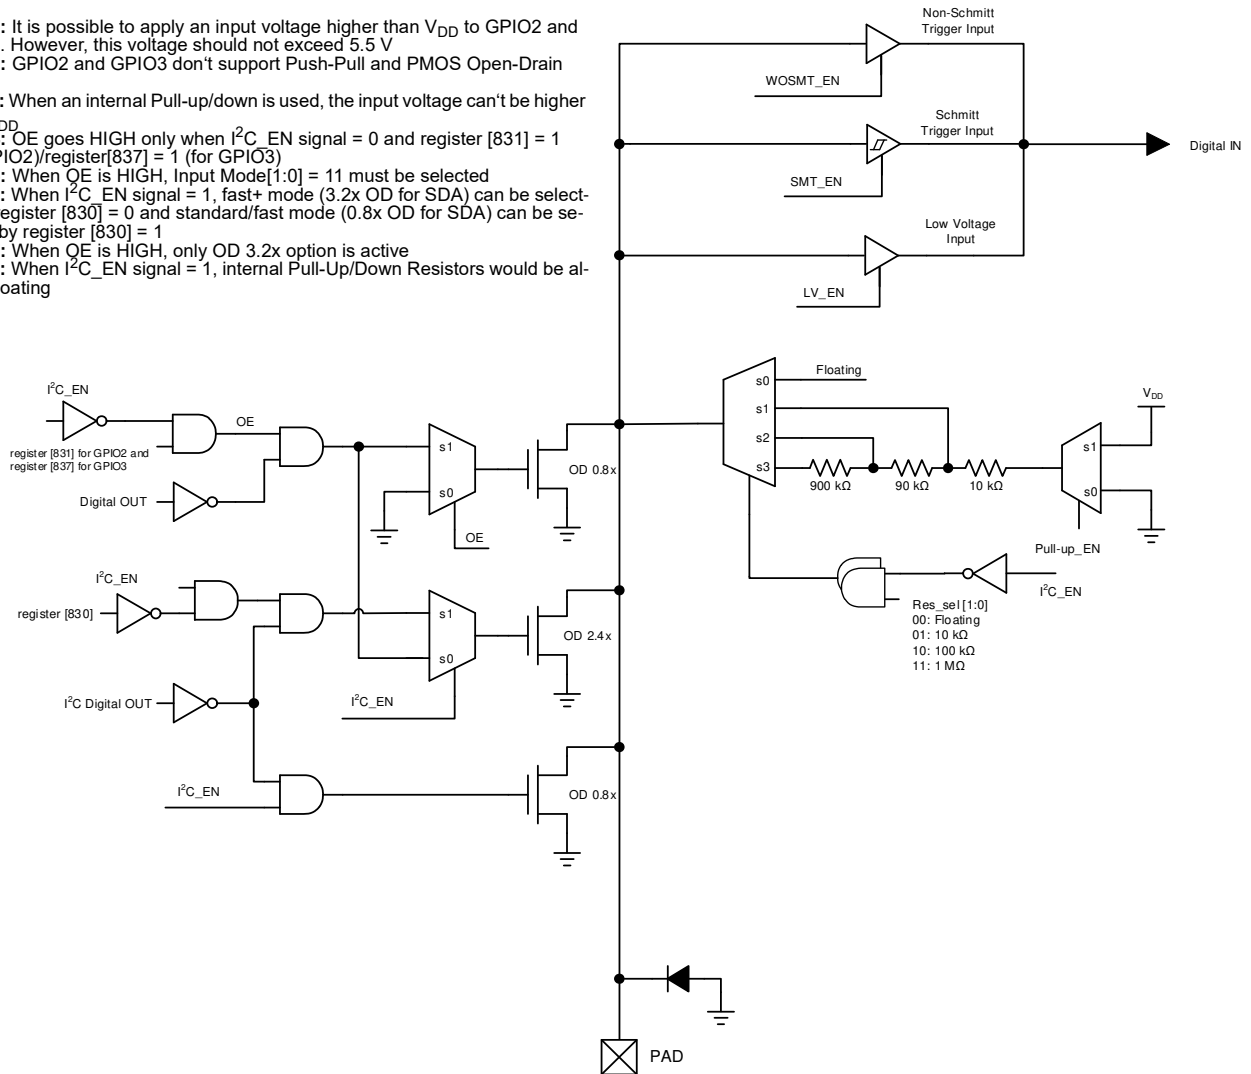

Figure 4: GPIO with I²C Mode Structure Diagram

Table 26: GPIO2 Mode Selection

Register [2032]	Register [831]	Register [830]	GPIO2 Mode
0	x	x	I ² C SCL
1	0	x	GPI, depends on registers [826:825]
1	1	x	GPO, 3.4x OD only

Table 27: GPIO3 Mode Selection

Register [2032]	Register [837]	Register [830]	GPIO3 Mode
0	x	0	I ² C SDA, fast+
0	x	1	I ² C SDA, standard/fast
1	0	x	GPI, depends on registers [833:832]
1	1	x	GPO, 3.4x OD only

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

6.8 MATRIX OE IO STRUCTURE (FOR V_{DD} GROUP)

6.8.1 Matrix OE IO Structure (for GPIOs 0, 1, 4, 5, 6)

Input Mode [1:0]
 00: Digital In without Schmitt Trigger, WOSMT_EN = 1, OE = 0
 01: Digital In with Schmitt Trigger, SMT_EN = 1, OE = 0
 10: Low Voltage Digital In mode, LV_EN = 1, OE = 0
 11: Analog IO mode

Output Mode [1:0]
 00: Push-Pull 1x mode, PP1x_EN = 1, OE = 1
 01: Push-Pull 2x mode, PP2x_EN = 1, PP1x_EN = 1, OE = 1
 10: NMOS 1x Open-DRAIN mode, OD1x_EN = 1, OE = 1
 11: NMOS 2x Open-DRAIN mode, OD2x_EN = 1, OD1x_EN = 1, OE = 1

Note 1: Digital OUT and OE are Matrix Output, Digital In is Matrix Input
 Note 2: Can be varied over PTV, for reference only

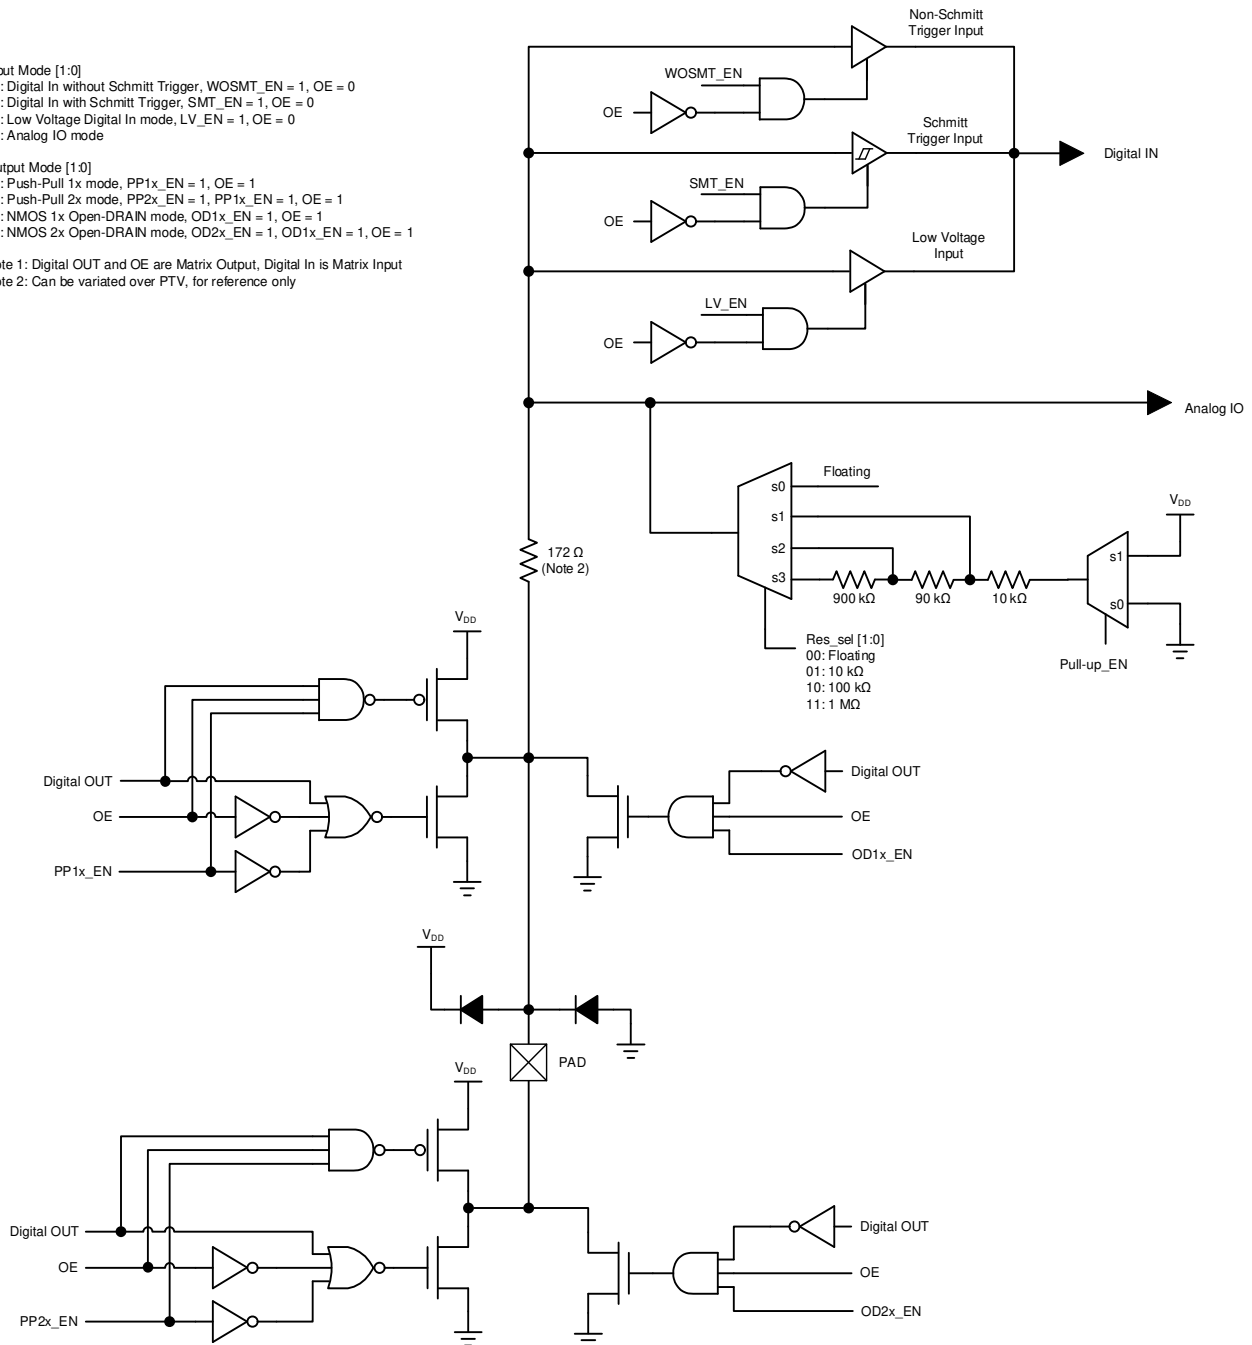

Figure 5: GPIO Matrix OE IO Structure Diagram

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

6.9 GPO MATRIX OE STRUCTURE (FOR V_{DD2} GROUP)

Using sleep mode to minimize supply current should be sufficient under normal operation.

Outputs HV GPO0, HV GPO1, HV GPO2, HV GPO3 have individual HV_SLEEP Input signal. If Sleep Input is active, Charge Pumps are disabled, and H-bridge FETs are set to Hi-Z state.

6.9.1 GPO with Matrix OE Structure (for HV GPOs 0 and 1)

Output Mode registers [777:776] for HV_GPO_0, registers [785:784] for HV_GPO_1:
 00: Hi-Z mode (High Impedance)
 01: NMOS 1x LOW SIDE Open-DRAIN mode (Open-DRAIN LOW side On)
 10: NMOS 1x HIGH SIDE Open-DRAIN mode (Open-DRAIN HIGH side On)
 11: Push-Pull 1x mode (Open-DRAIN HIGH and LOW sides On)

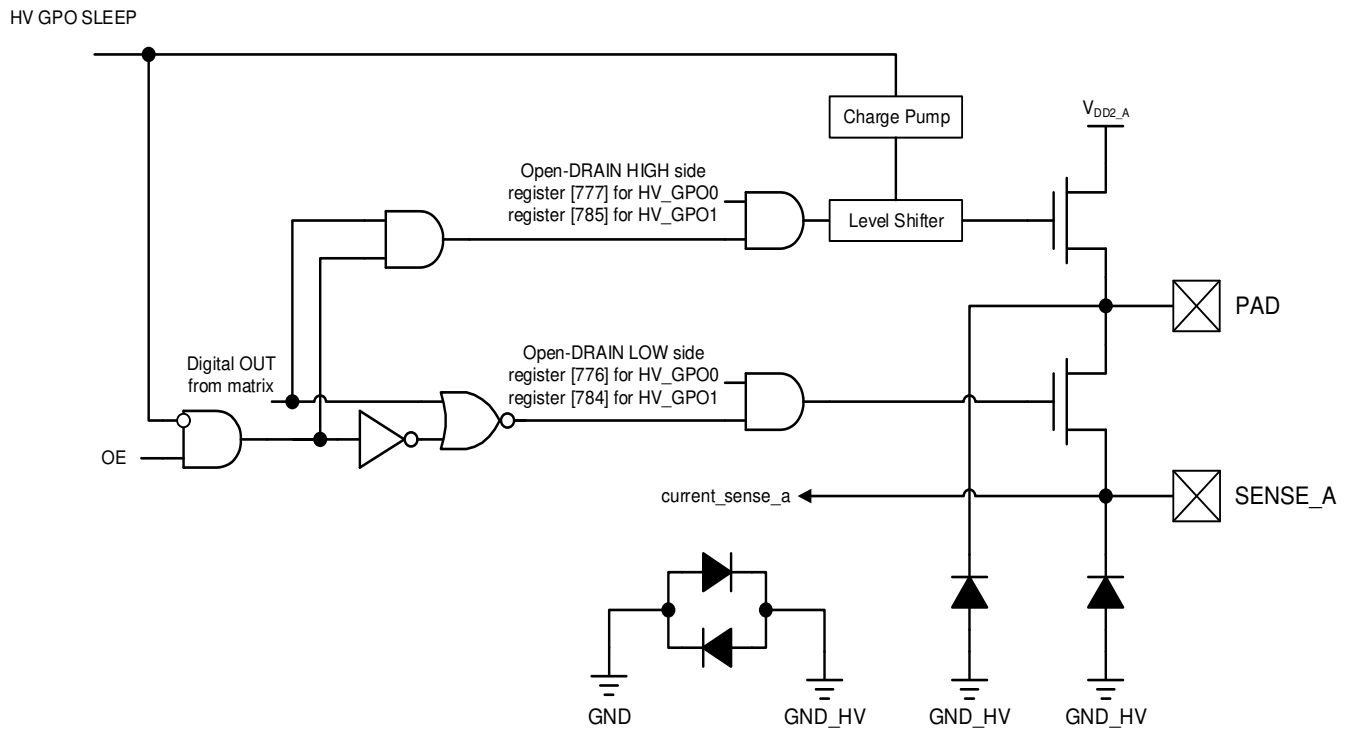

Figure 6: HV GPO Matrix OE IO Structure Diagram

 11: Push-Pull 1x mode (Open-DRAIN HIGH and LOW sides On)

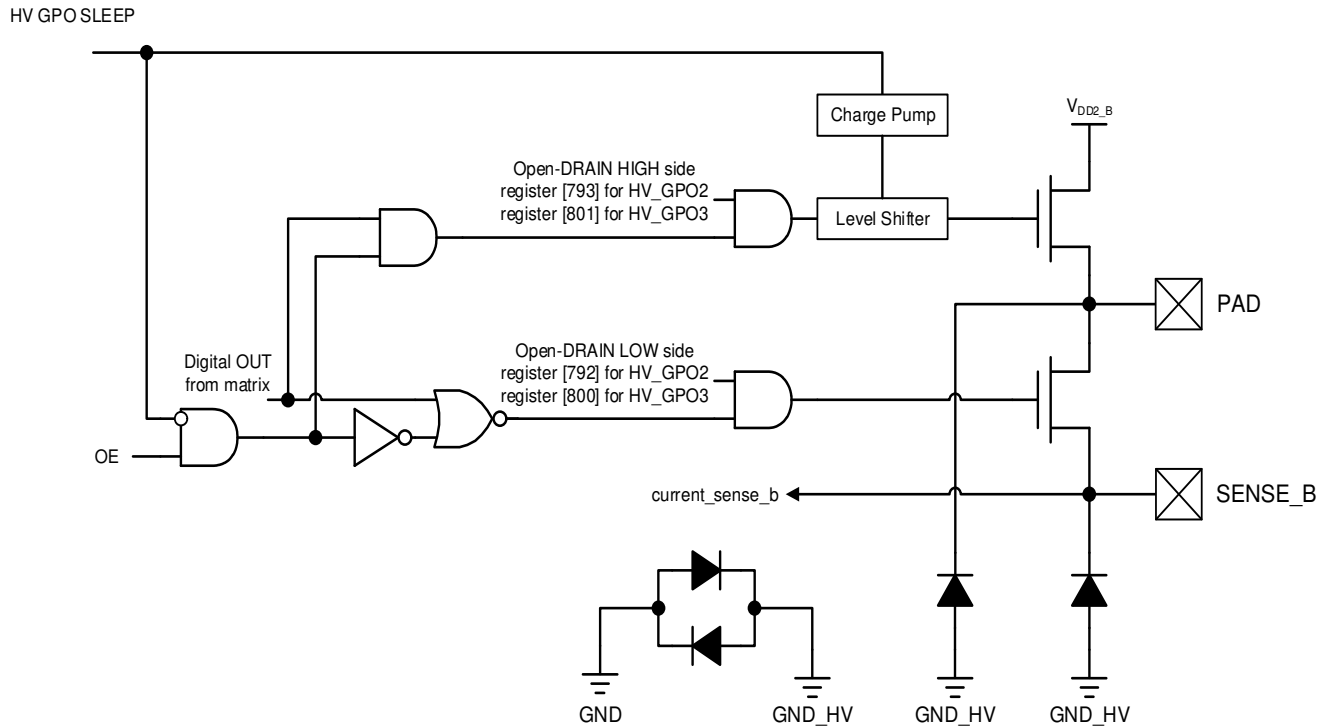

Figure 7: HV GPO Matrix OE IO Structure Diagram

7 High Voltage Output Modes

The device integrates four High Drive Half bridges, PWM voltage regulation method, current regulation circuitry, and protection circuits, including dead band circuit.

HV GPOs work as power PINs, so if two bridges open simultaneously for any reason, for example, timing desynchronization, it will result in cross-conduction (shoot-through) between the two bridges and damage the chip. To avoid this, t_{DEAD} is entered between switching on upper and lower power transistors. During output state transition from LOW to HIGH, the lower NMOS turns off and only after t_{DEAD} the upper NMOS turns on. While t_{DEAD} the PIN is in Hi-Z state. The same process is applied when transiting from HIGH to LOW. t_{DEAD} is different for DRIVER and PREDRIVER modes.

The user can select Modes of HV Outputs:

- Full-Bridge Mode;
- Half-Bridge Mode;
- Pre-Driver Mode.

PWM Voltage regulation is useful for designs where there is a need to maintain constant motor speed with changeable power supply level. When the High V_{DD2} is decreasing (battery discharging), it's possible to increase PWM duty cycle, and when the High V_{DD2} is increasing (battery charging) it's possible to decrease PWM duty cycle. It's possible to turn off the PWM and HV GPO for battery saving when the motor is idle, and others.

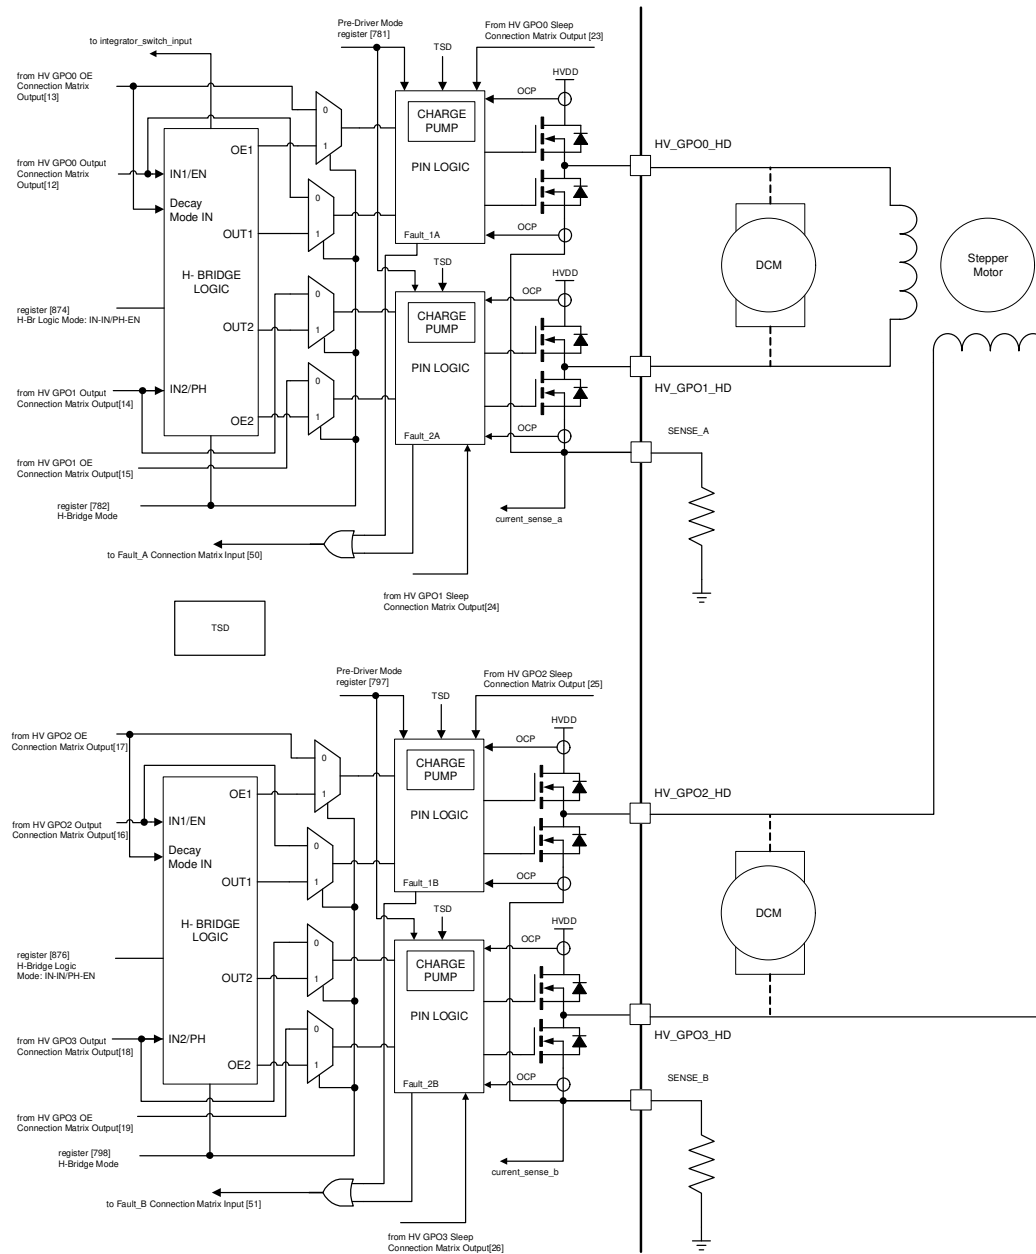

Figure 8: HV OUT Block Diagram

7.1 FULL-BRIDGE MODE

Full-Bridge (H-bridge) mode is selected by setting register [782] and register [798] to 1 for HV_GPO0/HV_GPO1 and HV_GPO2/HV_GPO3 respectively. In this mode, HV GPO0 functions in couple with HV GPO1 and HV GPO2 functions in couple with HV GPO3. This mode is useful for driving up to two DC motors with the ability to change the motors rotation direction. Also, this mode can be used to drive one Stepper Motor as shown in Figure 9.

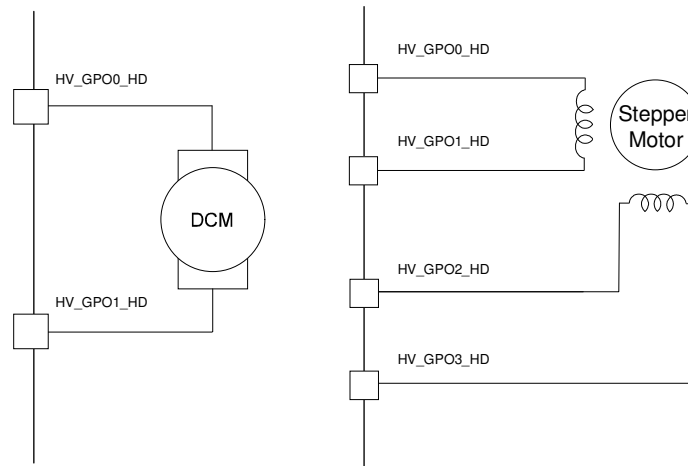

Figure 9: Full-Bridge Mode Operation

OE inputs of high voltage pins aren't used in Full-Bridge mode except HV GPO0 OE input and HV GPO2 OE input in PH-EN sub-mode, where these inputs are used to select Decay Mode for each of H-Bridges.

Note : All 4 Sleep pins in this mode are active separately.

Other inputs and outputs operate depending on Control_Sel register [874] and register [876] for HV_GPO0/HV_GPO1 and HV_GPO2/HV_GPO3 respectively as shown in Table 28 and Table 29.

Table 28: H-Bridge Logic Control Selection Register = 0 (IN-IN Mode)

HV H-Bridge Sleep	Digital OUT1	Digital OUT2	HV GPO0	HV GPO1	Function
1	X	X	Hi-Z	Hi-Z	Off (Coast)
0	0	0	Hi-Z	Hi-Z	Coast
0	0	1	L	H	Reverse
0	1	0	H	L	Forward
0	1	1	L	L	Brake

Table 29: H-Bridge Logic Control Selection Register = 1 (PH-EN Mode)

HV H-Bridge Sleep	Decay Mode IN (HV GPO0 OE)	Digital OUT1 (EN/PWM)	Digital OUT2 (PH/Direct)	HV GPO0	HV GPO1	Function
1	X	X	X	Hi-Z	Hi-Z	Off (Coast)
0	0 (Fast Decay)	0	X	Hi-Z	Hi-Z	Coast
0	1 (Slow Decay)	0	X	L	L	Brake
0	X	1	0	H	L	Forward
0	X	1	1	L	H	Reverse

HV GPO0, HV GPO1, HV GPO2, and HV GPO3 are tri-state Pins, which can't be pulled up/down internally.

The HV GPOs can be used to control the motor speed with the help of PWM technique. Fast decay mode causes a rapid reduction in inductive current and allows the motor to coast toward zero velocity. Slow decay mode leads to a slower reduction

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

in inductive current, but produces rapid deceleration.

For IN-IN mode, to drive DC motor in fast-decay mode, the PWM signal should be applied to one HV GPOx pin, while the other is held in the logic LOW state. To use slow-decay mode, one HV GPOx pin should be sourced by PWM signal, while the opposite pin is held in the logic HIGH state.

Table 30: PWM Control of Motor Speed (IN-IN Mode)

Function	Digital OUT1	Digital OUT2
Forward PWM, fast decay	PWM	0
Forward PWM, slow decay	1	PWM
Reverse PWM, fast decay	0	PWM
Reverse PWM, slow decay	PWM	1

PH-EN mode is convenient for H-Bridge control by internal PWM macrocell, because PWM signal is connected to Digital OUT1 input only. In this case there is no need to use an additional MUXs. Rotation direction is changed by Digital OUT2 input.

Table 31: PWM Control of Motor Speed (PH-EN Mode)

Function	Digital OUT1	Digital OUT2	Decay Mode IN
Forward PWM, fast decay	PWM	0	0
Reverse PWM, fast decay	PWM	1	0
Forward PWM, slow decay	PWM	0	1
Reverse PWM, slow decay	PWM	1	1

Figure 10 shows the current paths in a different drive and decay modes.

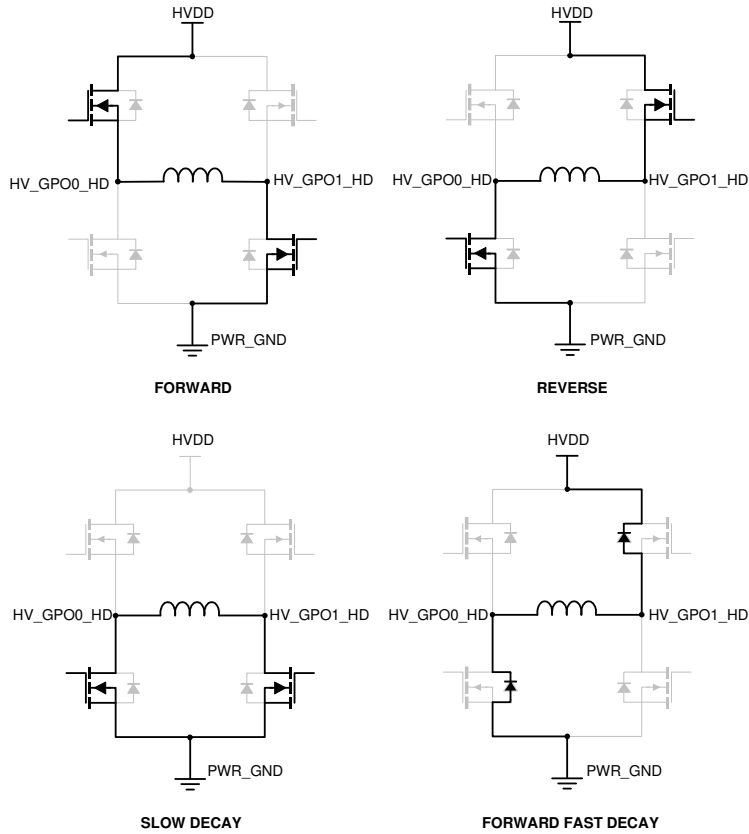

Figure 10: Drive and Decay Modes

7.2 HALF BRIDGE MODE

Half-Bridge Mode is selected by setting register [782] and register [798] to 0 for HV_GPO0/HV_GPO1 and HV_GPO2/HV_GPO3 respectively. This mode is the default mode for HV GPO pins. In this mode, there is a possibility to drive up to four motors spinning in one direction.

Figure 11: Half-Bridge Mode Operation

In Half-Bridge mode HV GPO will work as shown in [Table 32](#).

Table 32: Half-Bridge Logic

Function	HV GPO Sleep	OE	Digital OUT	HV GPO
Off	1	X	X	Hi-Z
Off (Coast)	0	0	X	Hi-Z
Brake	0	1	0	L
Forward	0	1	1	H

7.3 PRE-DRIVER MODE

This mode is activated by setting register [781] and register [797] to 1 for HV_GPO0/HV_GPO1 and HV_GPO2/HV_GPO3 respectively. The difference of this mode is that the rise time t_R and fall time t_F of High Drive HV GPO MOSFETs are much smaller than in regular mode. This allows using SLG47105 as a driver for external transistors.

When this mode is active, user can configure HV GPO to work in Full-Bridge or Half-Bridge Modes, as well as in regular mode (Pre-Driver Mode is disabled, registers [781] / [797] = 0).

7.4 PARALLEL CONNECTION OF HV GPO

The user can connect outputs in parallel to increase current rating. Note that this regime has no special register for activation.

To work in parallel Full-bridge Mode, the user must connect HV_GPO0_HD with HV_GPO2_HD and HV_GPO1_HD with HV_GPO3_HD. [Figure 12](#) shows a simplified schematic of DC motor connected to parallel H-Bridge of SLG47105.

Note that user can configure HV GPO outputs in Half-bridge Mode and connect them in parallel. In this case, user must take care of HV GPO control to prevent short circuit.

Figure 12: Parallel Connection of HV GPOs for Full-Bridge Mode

7.5 PROTECTION CIRCUITS

7.5.1 General FAULT signals

The SLG47105 has five FAULT signals. Two of them are FAULT_A and FAULT_B. They are the general signals which consist of all available FAULT signals for both V_{DD2_A} and V_{DD2_B} separately.

FAULT_A:

- Over-current Protection OCP_A
- Thermal Shutdown
- Under-voltage Lockout

FAULT_B:

- Over-current Protection OCP_B
- Thermal Shutdown
- Under-voltage Lockout

For more information on each of FAULT signals see Section 7.5.3 (Over-current Protection), Section 7.5.4 (Thermal Shutdown), and Section 7.5.5 (Under-voltage Lockout).

7.5.2 Advanced Current Control

A current control circuit is provided to regulate the system in the event of an overcurrent condition, for example, an abnormal mechanical load of DC motor. This circuit can be used for implementing constant current closed loop systems or for current limitation.

The current is sensed by external sense resistors connected to SENSE_A and SENSE_B Pins. Two current comparators are used to convert these currents to logic level. Using a current comparator with PWM block, output current can be dynamically changed. For example, for a stepper motor for micro stepping it is possible to set 16 values for sinusoidal current limit form.

7.5.3 Over-current Protection (OCP)

Each of FETs has an analog current limit circuit for turning off FETs when the current exceeds the threshold. When the overcurrent (I_{OCP}) persists for longer than the t_{OCP1} time, the FETs in the Half-Bridge are disabled, and FAULT signal to matrix driven high. t_{OCP1} time is optional. It can be enabled by register [873] for HV GPO0/1 and by register [875] for HV GPO2/3. When this option is disabled, OCP circuit reacts immediately without deglitch time. The FETs will be disabled along t_{OCP2} time when the current decreases to a normal value. t_{OCP2} could be changed by setting the registers (HV GPO0 - registers[780:778], HV GPO1 - registers[788:786], HV GPO2 - registers[796:794], HV GPO3 - registers[804:802]). Overcurrent conditions are detected for both high- and low-side FETs. There are special type of matrix input FAULTs, first one is personal matrix input [60]

for OCP_FAULT_A and another one is personal matrix input [61] for OCP_FAULT_B.

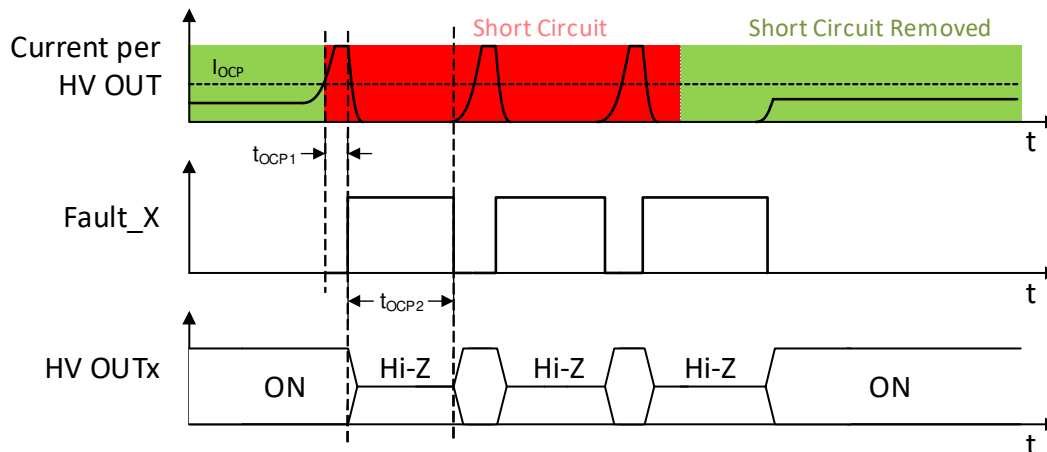

Figure 13: Overcurrent Protection Operation

7.5.4 Thermal Shutdown (TSD) and Thermal Considerations

If the die temperature exceeds safe limits T_{SD} , all output FETs in each H-/Half-bridge are disabled. After the die temperature has fallen to a safe level, operation automatically resumes. Note that TSD is active only during HV GPOs are wake. When all HV GPOs are in Power-down, TSD function is inactive. The SLG47105 has a special package optimized for better heat dissipation. All HV output pins and central plates should be thermally connected to copper traces or pads on the PCB for better heat dissipation. It is recommended to use thermal vias under the Ground and V_{DD} plates for the better thermal characteristic. TSD_FAULT signal is connected to Matrix Input [62]. TSD_FAULT signal is also present in FAULT_A and FAULT_B signals.

7.5.5 Under-voltage Lockout (UVLO)

When the voltage on the pin V_{DD2} is less than the V_{UVLO} , then the HV_GPOx outputs are disabled, Fault_A and Fault_B outputs are driven HIGH. When the voltage rises to the minimal V_{DD2} voltage, then the Fault outputs is driven LOW and work is restored.]

UVLO can be enabled separately for V_{DD2_A} and V_{DD2_B} by register [864]/[865].

7.6 PWM VOLTAGE CONTROL

The SLG47105 provides the ability to control the voltage applied to the motor winding. This feature allows achieving constant motor speed during supply voltage variations.

To use this function, the user needs to enable H-Bridge mode and use the integrator on first H-Bridge, which consists of HV_GPO0_HD and HV_GPO1_HD Pins. The integrator output is connected to the positive input of separate Analog Comparator. Also, Vref value on the negative comparator input must be selected. The integrator monitors the voltage difference between HV_GPO0_HD and HV_GPO1_HD Pins of H-Bridge and integrates it to get an average voltage value.

The outputs of the comparator must be connected to the PWM block with or without an additional logic circuit. If the average output voltage is lower than Vref, the duty cycle of the PWM output needs to increase; if the average output value is higher than Vref, the duty cycle needs to decrease; when the average output value is equal to Comparator threshold, PWM duty cycle is kept by EQUAL output.

Note that if the desired output voltage (reference of ACMP) is greater than the supply voltage, the device will operate at 100 % duty cycle and the voltage regulation feature will be disabled. In this mode the device behaves as a conventional H-Bridge driver.

8 Differential Amplifier with Integrator and Comparator

Differential Amplifier with Integrator and Analog Comparator is connected to HV_GPO0_HD and HV_GPO1_HD (first H-Bridge). This macrocell is useful when there is a need to keep the constant voltage at H-Bridge load. Differential Amplifier with Integrator and Comparator has dedicated power-up input control (Connection Matrix output). During LOW on power-up input the Differential Amplifier with Integrator and Comparator is in power down state and its outputs are latched in previous state.

"Upward" output of macrocell is active HIGH when Average Voltage Difference on H-Bridge (integrated Voltage) is higher than upper Vref of Comparator (including Differential Amplifier influence). "Upward" output can be optionally inverted by setting register [753] to 1.

"Equal" output is active HIGH when integrated Voltage is equal to Comparator Threshold.

The inputs of the Differential Amplifier can be:

-HV_GPO0_HD or HV_GPO1_HD outputs for non-inverting ("+") input;

-HV_GPO1_HD or HV_GPO0_HD outputs for inverting ("-") input.

The internal multiplexer connects HV_GPOx_HD Pins to Differential Amplifier inputs in right combination automatically, depending on H-Bridge logic inputs current state (in H-Bridge Mode only).

The Comparator IN- voltage source is internal 0 - 2.016 V with 32 mV step or external voltage (GPIO0). There is 0.25x Gain divider after Differential Amplifier.

The Differential Amplifier operation conditions:

- PWM0 is enabled
- HV OUT CTRL0 is configured in H-Bridge mode
- PWM frequency 44 kHz or higher to make sure that Integrator operates correctly.

The integrated DC voltage level is applied to the comparator positive input. The comparator outputs are used to control the PWM duty cycle. In this case, a closed loop system controls the PWM duty cycle to ensure the constant average output voltage level.

Note that PWM duty cycle CNT CLK requires the rate of update at latest two PWM period cycles or more.

Differential Amplifier with Integrator and Analog Comparator macrocell operates synchronously to PWM0 macrocell. So, to use Differential Amplifier with Integrator and Analog Comparator it is necessary to enable PWM0 macrocell and Oscillator, used by this PWM macrocell.

It's recommended not to use Hi-Z state of HV_GPO0_HD and HV_GPO1_HD Pins when working with Differential Amplifier with Integrator and Comparator macrocell. Hi-Z state can decrease the accuracy of Differential Amplifier and may cause thermal shut down due to current flow through the diodes in the HV outputs, when Hi-Z state is enabled.

8.1 DIFFERENTIAL AMPLIFIER WITH INTEGRATOR BLOCK DIAGRAM

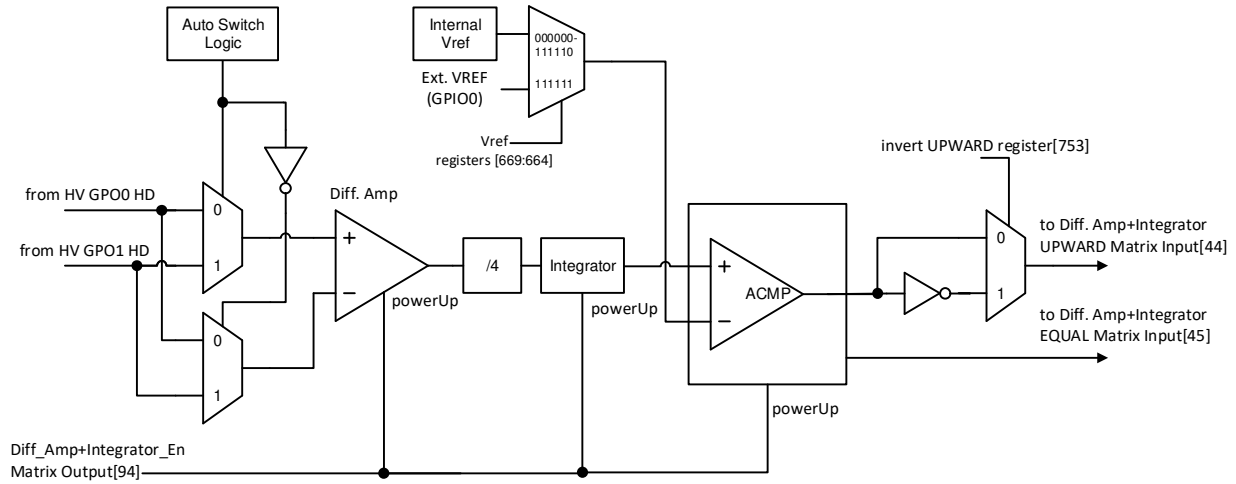

Figure 14: Differential Amplifier with Integrator Block Diagram

9 Current Sense Comparator

There are two Current Sense Comparator macrocells in the SLG47105.

Each of the Current CMP macrocells has a positive input signal that is connected to SENSE_x pins through Selectable Gain block. The options for Selectable Gain are 4x or 8x.

Each of the Current CMP macrocells has a negative input signal that can be connected to static or dynamic variable Vref. The static Vref value is selected via registers. The dynamically changed Vref values are selected with the help of one of the PWM blocks, different for each Current Sense Comparator. In this case, 6-bit Vref is selected by 6 Low Significant bits of Synchro Buffer, which is a part of the PWM block (detailed in Section 13). For example, the Current Sense Comparator Vref can be changed "on the flight" from 16-bytes Register File, which is connected to the Synchro Buffer by PWM block settings, and where user-defined Vref values are stored. The Vref values are switched Up or Down depending on the level of PWM macrocell Up/Down input, each pulse on DUTY_CYCLE_CLK input.

Note 1: The PWM block can be active when 16-bytes Register File is used by Current Sense Comparator.

Note 2: The Vref can be changed in a range from 32 mV to 2016 mV with 32 mV step.

During power-up, the Current Sense Comparator output will remain LOW, and then become valid 12.5 μs (max) after power-up signal goes high.

Current Sense Comparator0 IN+ is connected with SENSE_A pin through Selectable Gain0.

Current Sense Comparator1 IN+ is connected with SENSE_B pin through Selectable Gain1.

9.1 CURRENT SENSE COMPARATOR0 BLOCK DIAGRAM

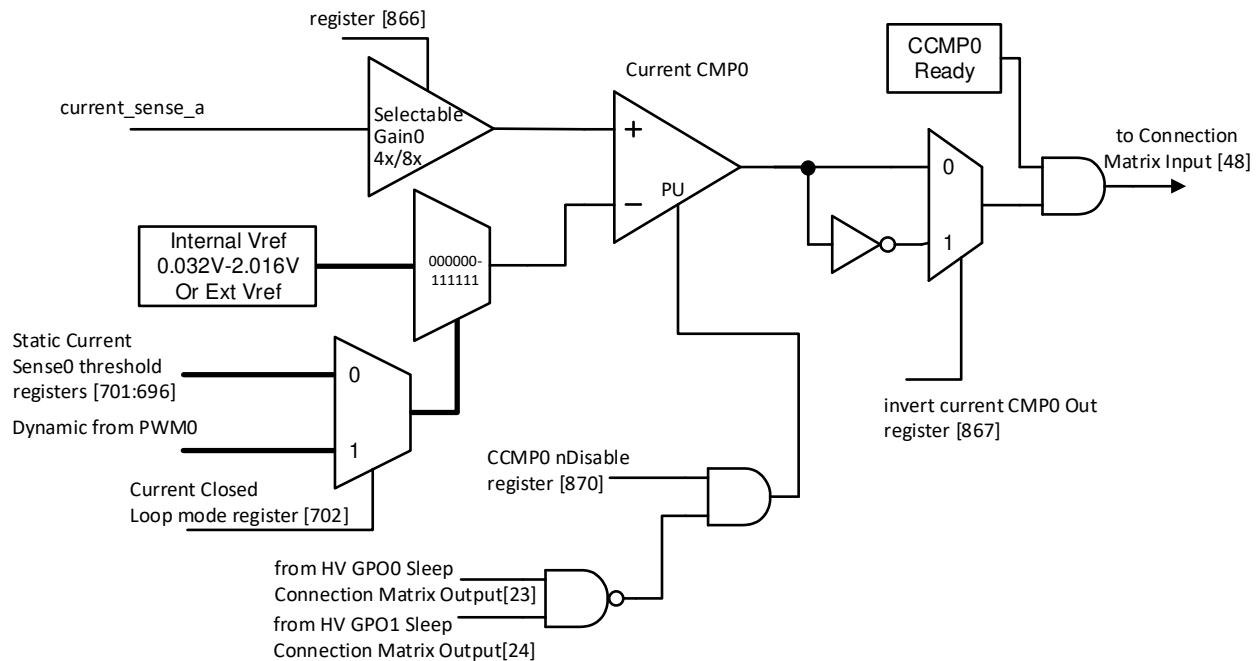

Figure 15: Current Sense Comparator0 Block Diagram

9.2 CURRENT SENSE COMPARATOR1 BLOCK DIAGRAM

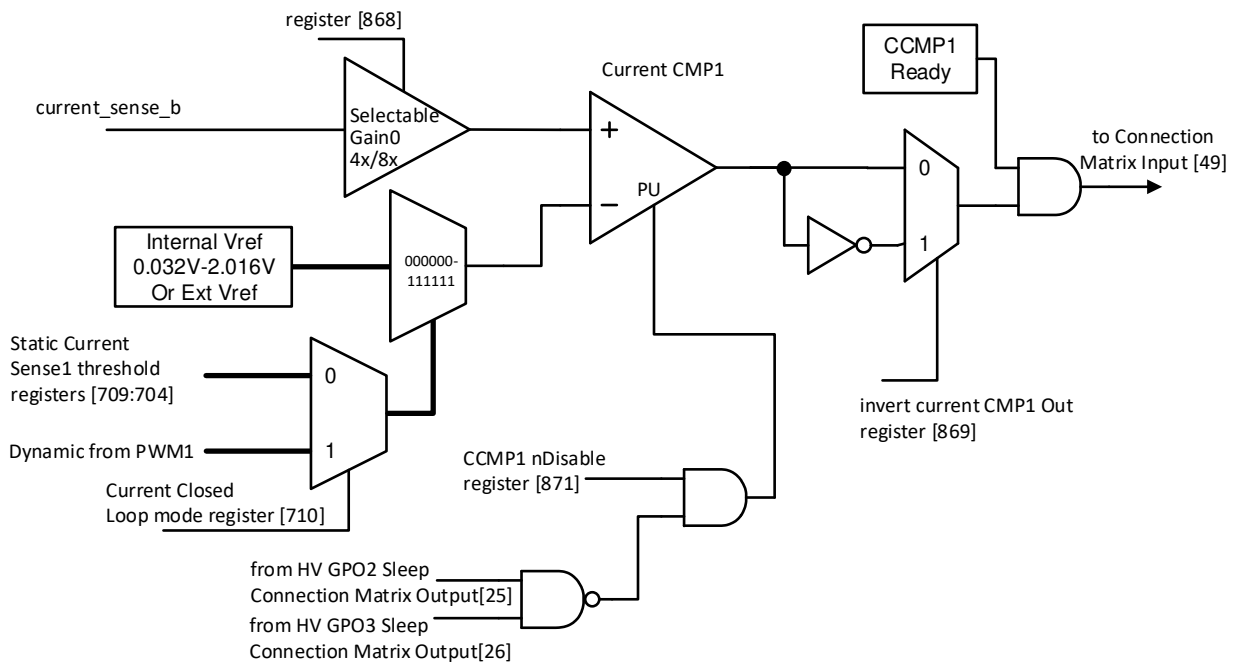

Figure 16: Current Sense Comparator1 Block Diagram

9.3 CURRENT REGULATION

To use the Current Regulation, it is necessary to connect sense-resistors between SENSE_x pins and ground. The resistor value is calculated by the formula:

$$I[n] = \frac{V_{ref}[n]}{R_{sense} \times GAIN}$$

Where:

- I[n]- Load Current (through controlled winding or resistive load) for selected $V_{ref}[n]$
- Vref - reference voltage of Current Sense Comparator, constant value, external source, or selectable value from Register File
- R_{SENSE} - resistance of the sense resistor
- GAIN - selectable gain (4x or 8x, selectable by the register)

The reference voltage can be set statically or dynamically. For static reference voltage setting it is required to calculate R_{SENSE} for selected reference voltage and desired motor current.

For dynamic reference voltage setting it is required to calculate R_{SENSE} for the maximal user-defined reference voltage and maximal current via motor winding.

16 values in the Reg File can be used to determine the shape of motor current, for example, sin current for the stepper motor.

DUTY_CYCLE_CLK input of PWM macrocell is used to switch to the next Vref value, and UP/DOWN input of PWM macrocell selects the direction of Vref change (next or previous Vref value). For more detailed description of Reg File see Section 13.

10 Connection Matrix

The Connection Matrix in the SLG47105 is used to create the internal routing for internal functional macrocells of the device once it is programmed. The registers are programmed from the one time programmable (OTP) NVM cell during Test Mode Operation. The output of each functional macrocell within the SLG47105 has a specific digital bit code assigned to it, that is either set to active “High”, or inactive “Low”, based on the design that is created. Once the 2048 register bits within the SLG47105 are programmed, a fully custom circuit will be created.

The Connection Matrix has 64 inputs and 96 outputs. Each of the 64 inputs to the Connection Matrix is hard-wired to the digital output of a particular source macrocell, including IO pins, LUTs, analog comparators, other digital resources, such as V_{DD} and GND. The input to a digital macrocell uses a 6-bit register to select one of these 64 input lines.

For a complete list of the SLG47105’s register table, see Section 23.

10.3 CONNECTION MATRIX VIRTUAL INPUTS

As mentioned previously, the Connection Matrix inputs come from the outputs of various digital macrocells on the device. Eight of the Connection Matrix inputs have the special characteristic that the state of these signal lines comes from a corresponding data bit written as a register value via I²C. This gives the user the ability to write data via the serial channel, and have this information translated into signals that can be driven into the Connection Matrix and from the Connection Matrix to the digital inputs of other macrocells on the device. The I²C address for reading and writing these register values is at 0x4C (76).

An I²C write command to these register bits will set the signal values going into the Connection Matrix to the desired state. A read command to these register bits will read either the original data values coming from the NVM memory bits (that were loaded during the initial device startup) or the values from a previous write command (if that has happened).

Table 35: Connection Matrix Virtual Inputs

Matrix Input Number	Matrix Input Signal Function	Register Bit Addresses (d)
32	I ² C_virtual_0 Input	[608]
33	I ² C_virtual_1 Input	[609]
34	I ² C_virtual_2 Input	[610]
35	I ² C_virtual_3 Input	[611]
36	I ² C_virtual_4 Input	[612]
37	I ² C_virtual_5 Input	[613]
38	I ² C_virtual_6 Input	[614]
39	I ² C_virtual_7 Input	[615]

10.4 CONNECTION MATRIX VIRTUAL OUTPUTS

The digital outputs of the various macrocells are routed to the Connection Matrix to enable interconnections to the inputs of other macrocells in the device. At the same time it is possible to read the state of each of the macrocell outputs as a register value via I²C. This option, called Connection Matrix Virtual Outputs, allows the user to remotely read the values of each macrocell output. The I²C addresses for reading these register values are registers [639:576]. Write commands to these same register values will be ignored (with the exception of the Virtual Input register bits at registers [615:608]).

11 Combination Function Macrocells

The SLG47105 has 12 combination function macrocells that can serve more than one logic or timing function. In each case, they can serve as a Look Up Table (LUT), or as another logic or timing function. See the list below for the functions that can be implemented in these macrocells.

- Three macrocells that can serve as either 2-bit LUT or as D Flip-Flop
- Four macrocells that can serve as either 3-bit LUTs or as D Flip-Flops with Set/Reset Input
- Two macrocells that can serve as either 3-bit LUTs, as D Flip-Flops with Set/Reset Input or as PWM Choppers
- One macrocell that can serve as either 3-bit LUT or as Pipe Delay/Ripple Counter
- One macrocell that can serve as either 2-bit LUT or as Programmable Pattern Generator (PGen)
- One macrocell that can serve as either 4-bit LUT or as D Flip-Flop with Set/Reset Input

Inputs/Outputs for the 12 combination function macrocells are configured from the connection matrix with specific logic functions being defined by the state of configuration bits.

When used as a LUT to implement combinatorial logic functions, the outputs of the LUTs can be configured to any user defined function, including the following standard digital logic devices (AND, NAND, OR, NOR, XOR, XNOR).

11.1 2-BIT LUT OR D FLIP-FLOP MACROCELLS

There are three macrocells that can serve as either 2-bit LUT or as D Flip-Flop. When used to implement LUT functions, the 2-bit LUT takes in two input signals from the connection matrix and produces a single output, which goes back into the connection matrix. When used to implement D Flip-Flop function, the two input signals from the connection matrix go to the data (D) and clock (CLK) inputs for the Flip-Flop, with the output going back to the connection matrix.

The operation of the D Flip-Flop and LATCH will follow the functional descriptions below:

DFF: CLK is rising edge triggered, then Q = D; otherwise Q will not change

LATCH: when CLK is Low, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is High).

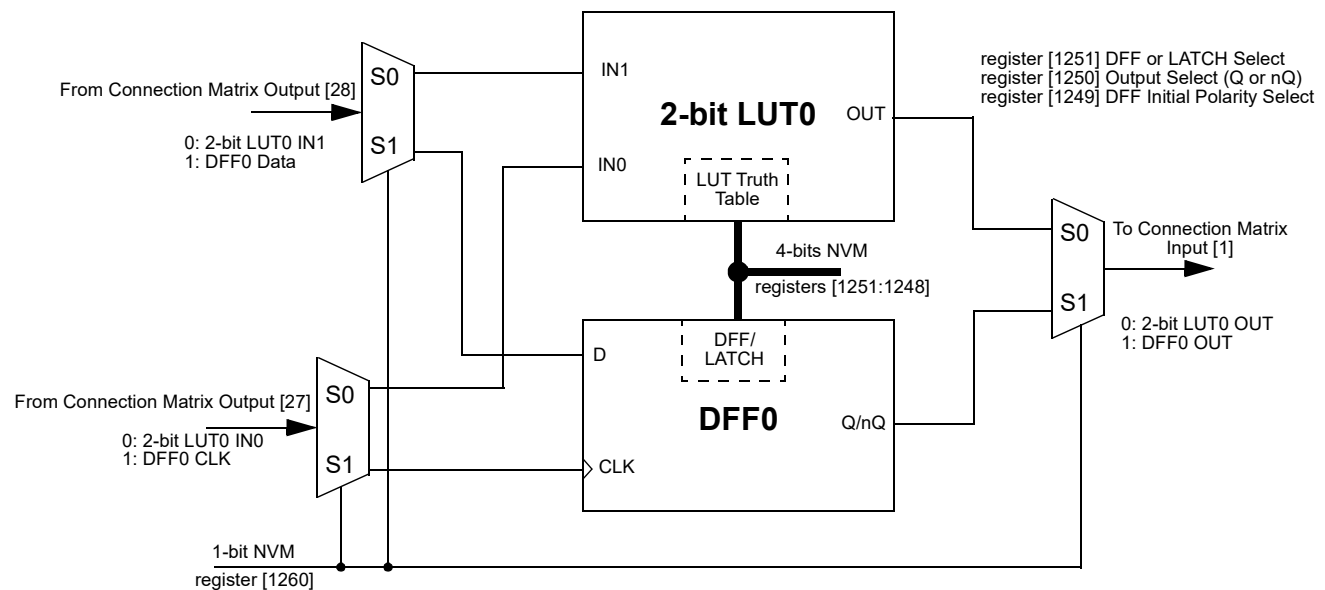

Figure 19: 2-bit LUT0 or DFF0

0	0	register [1256]	LSB
0	1	register [1257]	
1	0	register [1258]	
1	1	register [1259]	MSB

This macrocell, when programmed for a LUT function, uses a 4-bit register to define their output function:

2-bit LUT0 is defined by registers [1251:1248]

2-bit LUT1 is defined by registers [1255:1252]

2-bit LUT2 is defined by registers [1259:1256]

Table 39 shows the register bits for the standard digital logic devices (AND, NAND, OR, NOR, XOR, XNOR) that can be created within each of the 2-bit LUT logic cells.

Table 39: 2-bit LUT Standard Digital Functions

Function	MSB			LSB
AND-2	1	0	0	0
NAND-2	0	1	1	1
OR-2	1	1	1	0
NOR-2	0	0	0	1
XOR-2	0	1	1	0
XNOR-2	1	0	0	1

11.1.2 Initial Polarity Operations

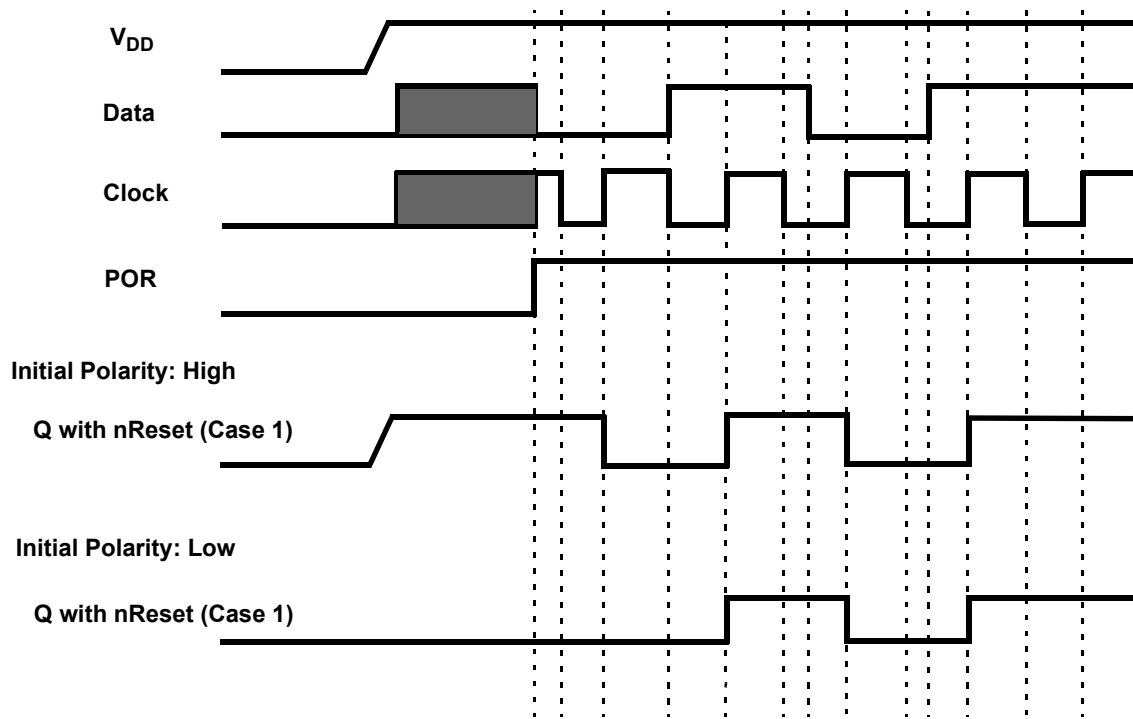

Figure 22: DFF Polarity Operations

11.2 2-BIT LUT OR PROGRAMMABLE PATTERN GENERATOR

The SLG47105 has one combination function macrocell that can serve as a logic or timing function. This macrocell can serve as a Look Up Table (LUT), or a Programmable Pattern Generator (PGen).

When used to implement LUT functions, the 2-bit LUT takes in two input signals from the connection matrix and produces a single output, which goes back into the connection matrix. When used as a LUT to implement combinatorial logic functions, the outputs of the LUT can be configured to any user-defined function, including the following standard digital logic devices (AND, NAND, OR, NOR, XOR, XNOR). The user can also define the combinatorial relationship between inputs and outputs to be any selectable function.

It is possible to define the RST level for the PGen macrocell. There are both high-level reset (RST) and a low-level reset (nRST) options available, which are selected by register [1193]. When operating as a Programmable Pattern Generator, the output of the macrocell will clock out a sequence of two to sixteen bits that are user selectable in their bit values, and user selectable in the number of bits (up to sixteen) that are output before the pattern repeats.

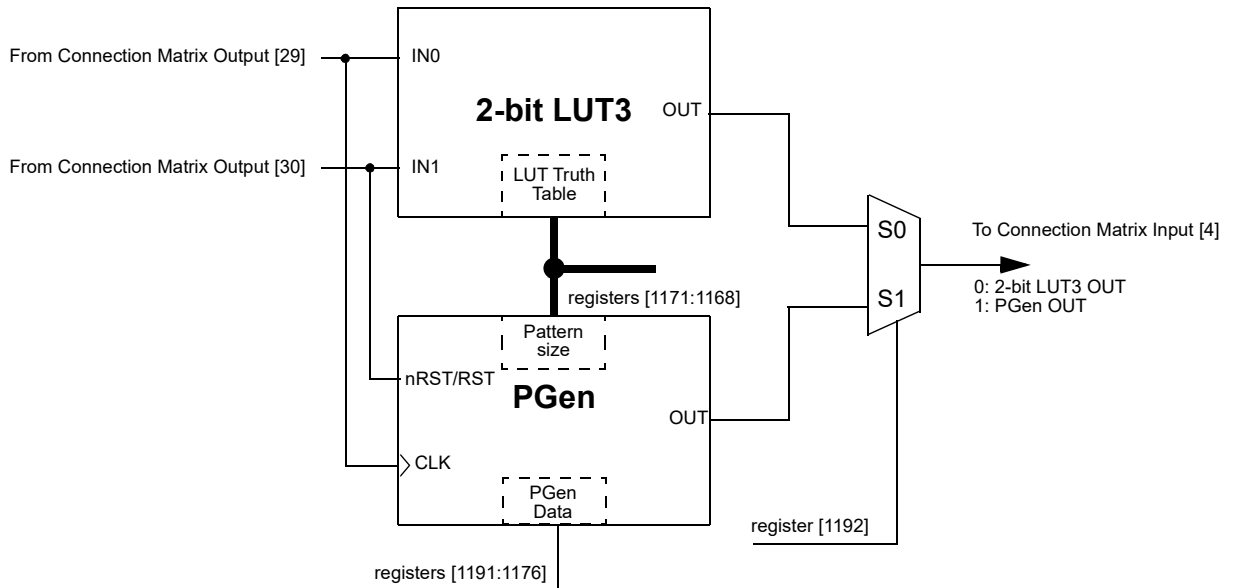

Figure 23: 2-bit LUT3 or PGen

Figure 24: PGen Timing Diagram

11.2.1 2-bit LUT or PGen Macrocell Used as 2-bit LUT

Table 40: 2-bit LUT1 Truth Table

0	0	register [1168]	LSB
0	1	register [1169]	
1	0	register [1170]	
1	1	register [1171]	MSB

This macrocell, when programmed for a LUT function, uses a 4-bit register to define their output function:

2-bit LUT3 is defined by registers [1171:1168]

Table 41 shows the register bits for the standard digital logic devices (AND, NAND, OR, NOR, XOR, XNOR) that can be created within each of the 2-bit LUT logic cells.

Table 41: 2-bit LUT Standard Digital Functions

Function	MSB			LSB
AND-2	1	0	0	0
NAND-2	0	1	1	1
OR-2	1	1	1	0
NOR-2	0	0	0	1
XOR-2	0	1	1	0
XNOR-2	1	0	0	1

11.3 3-BIT LUT OR D FLIP-FLOP WITH SET/RESET MACROCELLS

There are four macrocells that can serve as either 3-bit LUTs or as D Flip-Flops with Set/Reset inputs. When used to implement LUT functions, the 3-bit LUTs each takes in three input signals from the connection matrix and produces a single output, which goes back into the connection matrix. When used to implement D Flip-Flop function, the three input signals from the connection matrix go to the data (D) and clock (CLK), and Reset/Set (nRST/nSET) inputs for the Flip-Flop, with the output going back to the connection matrix. It is possible to define the active level for the reset/set input of DFF/LATCH macrocell. There are both active high level reset/set (RST/SET) and active low level reset/set (nRST/nSET) options available, which are selected by register [1226].

DFF3 functionality is different from the other DFFs. DFF3 operation will flow the functional description below:

- If register [1228] = 0, and the CLK is rising edge triggered, then Q = D, otherwise Q will not change.
- If register [1228] = 1, then data from D is written into the DFF by the rising edge on CLK and output to Q by the falling edge on CLK.

1	0	1	register [1245]	
1	1	0	register [1246]	
1	1	1	register [1247]	MSB

Each macrocell, when programmed for a LUT function, uses a 8-bit register to define their output function:

3-bit LUT0 is defined by registers [1231:1224]

3-bit LUT3 is defined by registers [1159:1152]

3-bit LUT4 is defined by registers [1167:1160]

3-bit LUT5 is defined by registers [1247:1240]

Table 46 shows the register bits for the standard digital logic devices (AND, NAND, OR, NOR, XOR, XNOR) that can be created within each of the four 3-bit LUT logic cells.

Table 46: 3-bit LUT Standard Digital Functions

Function	MSB							LSB

Figure 30: DFF Polarity Operations with nSet

11.4 3-BIT LUT OR D FLIP-FLOP WITH SET/RESET MACROCELL OR PWM CHOPPER

There are two macrocells that can serve as either 3-bit LUTs or as D Flip-Flops with Set/Reset inputs, or as PWM Chopper. When used to implement LUT functions, the 3-bit LUTs each takes in three input signals from the connection matrix and produces a single output, which goes back into the connection matrix. When used to implement D Flip-Flop function, the three input signals from the connection matrix go to the data (D) and clock (CLK), and Reset/Set (nRST/nSET) inputs for the Flip-Flop, with the output going back to the connection matrix. It is possible to define the active level for the reset/set input of DFF/LATCH macrocell. There are both active high-level reset/set (RST/SET) and active low-level reset/set (nRST/nSET) options available, which are selected by register [1139] and register [1147]. When used to implement PWM Chopper function, the three input signals from the connection matrix go to the PWM input (PWM) and Blanking Time input (Blanking Time), and Chopper input (Chop) for the PWM Chopper, with the output (OUT) going back to the connection matrix..

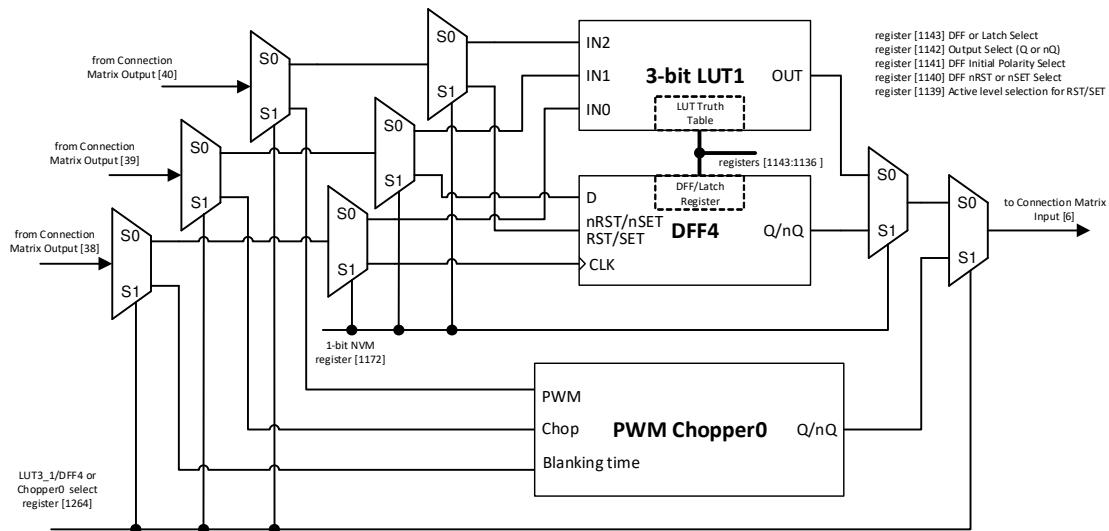

Figure 31: 3-bit LUT1 or DFF4

1	0	1	register [1149]	
1	1	0	register [1150]	
1	1	1	register [1151]	MSB

This macrocell, when programmed for a LUT function, uses a 8-bit register to define their output function:

3-bit LUT1 is defined by registers [1143:1136]

3-bit LUT2 is defined by registers [1151:1144]

Table 49 shows the register bits for the standard digital logic devices (AND, NAND, OR, NOR, XOR, XNOR) that can be created within each of the four 3-bit LUT logic cells.

Table 49: 3-bit LUT Standard Digital Functions

Function	MSB							LSB
AND-3	1	0	0	0	0	0	0	0
NAND-3	0	1	1	1	1	1	1	1
OR-3	1	1	1	1	1	1	1	0
NOR-3	0	0	0	0	0	0	0	1
XOR-3	1	0	0	1	0	1	1	0
XNOR-3	0	1	1	0	1	0	0	1

11.4.2 PWM chopper

PWM Chopper function can be used to chop PWM Duty Cycle by Current Comparator signal.

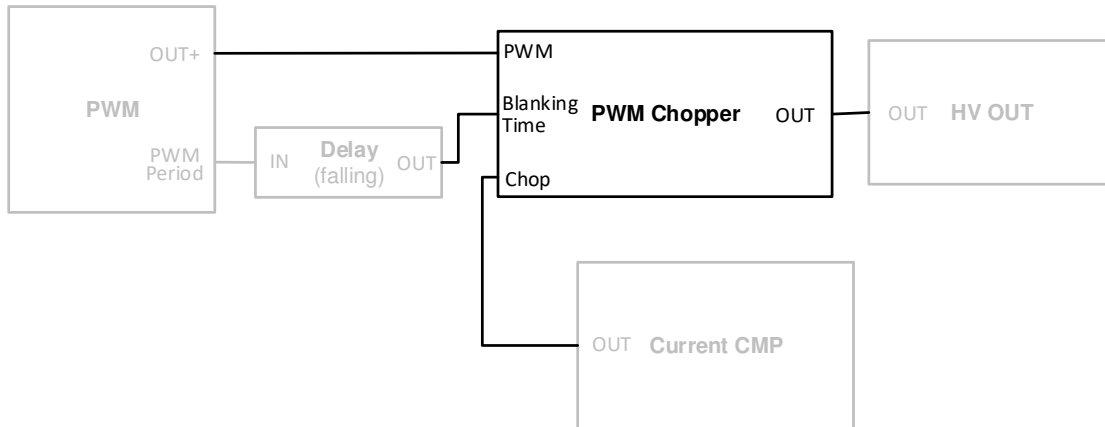

Figure 33: PWM Chopper Circuit Example

In PWM Chopper mode all internal components of 3-bit LUT or D Flip-Flop, or PWM Chopper Macrocell are connected as shown in Figure 34.

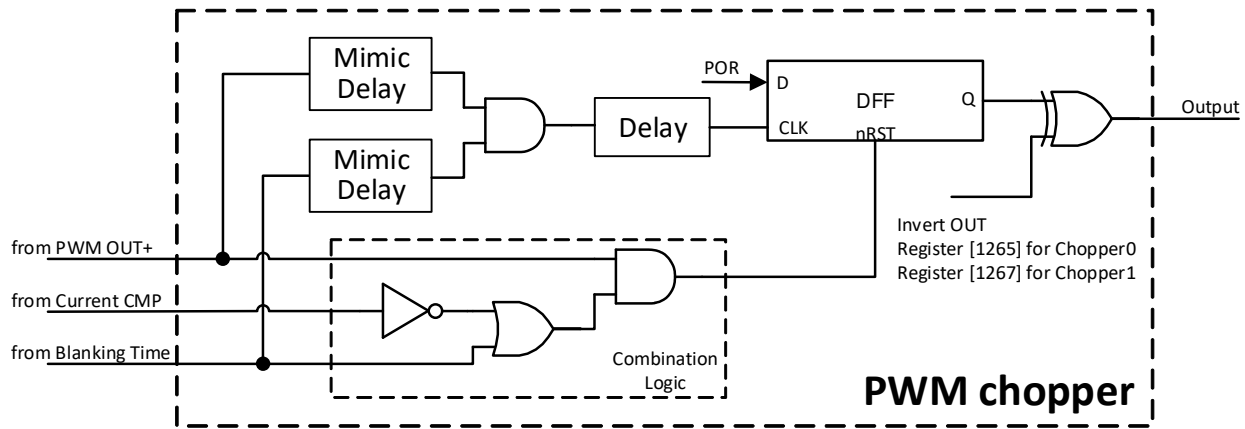

Figure 34: PWM Chopper Interconnection

This configuration allows ignoring Current Comparator signal during Blanking time during the motor start period. Any active signal from Current CMP after Blanking time causes PWM Duty Cycle chopping to currently Period end. The following figures demonstrate PWM Chopper operation.

Figure 35: PWM Chopper. Overcurrent Timing Diagram

11.4.3 Initial Polarity Operations

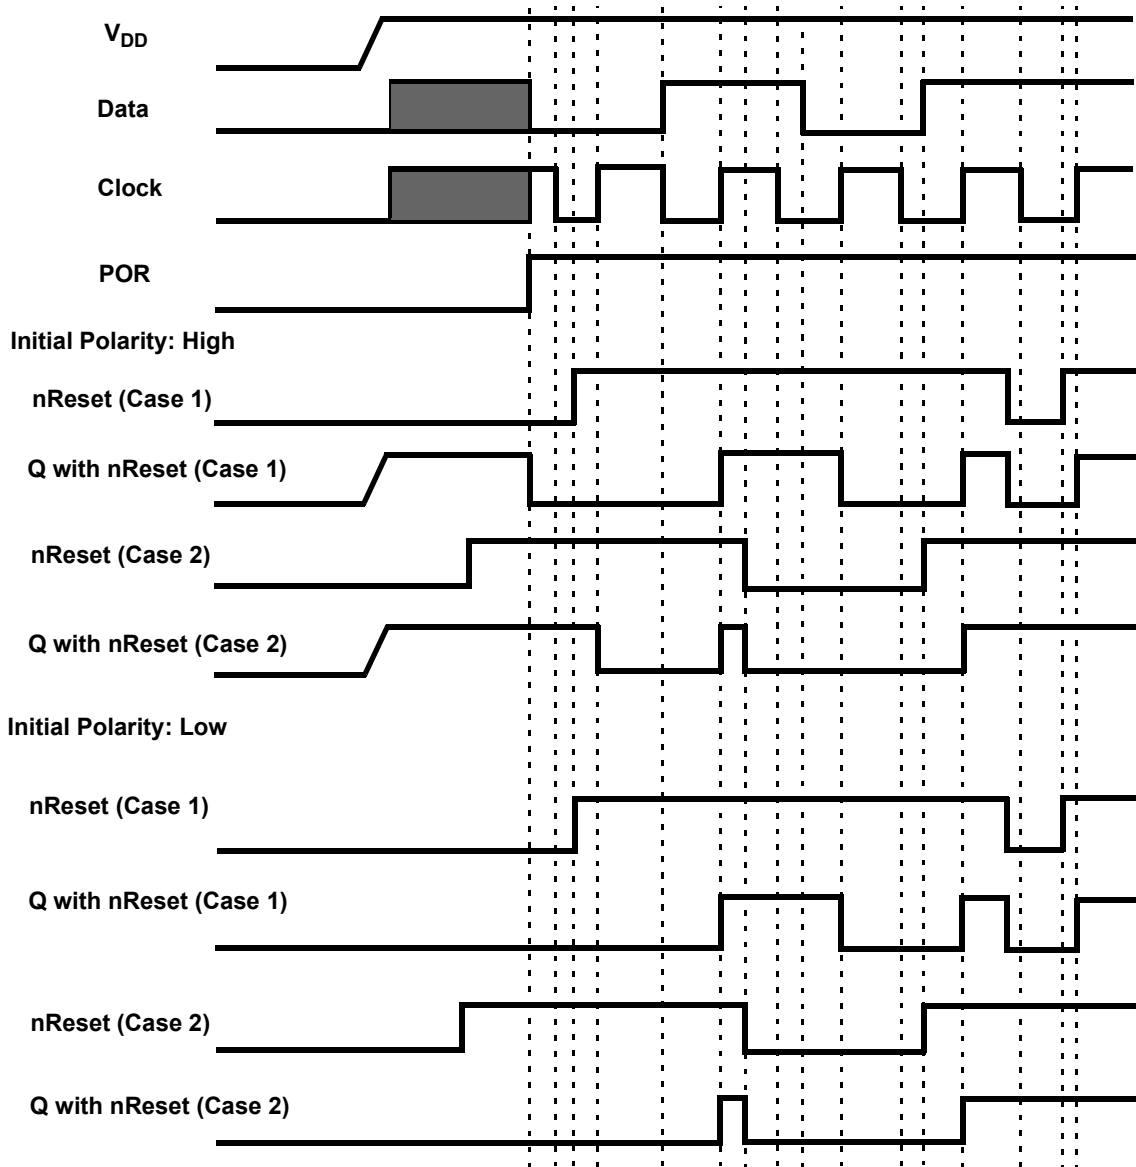

Figure 40: DFF Polarity Operations with nReset

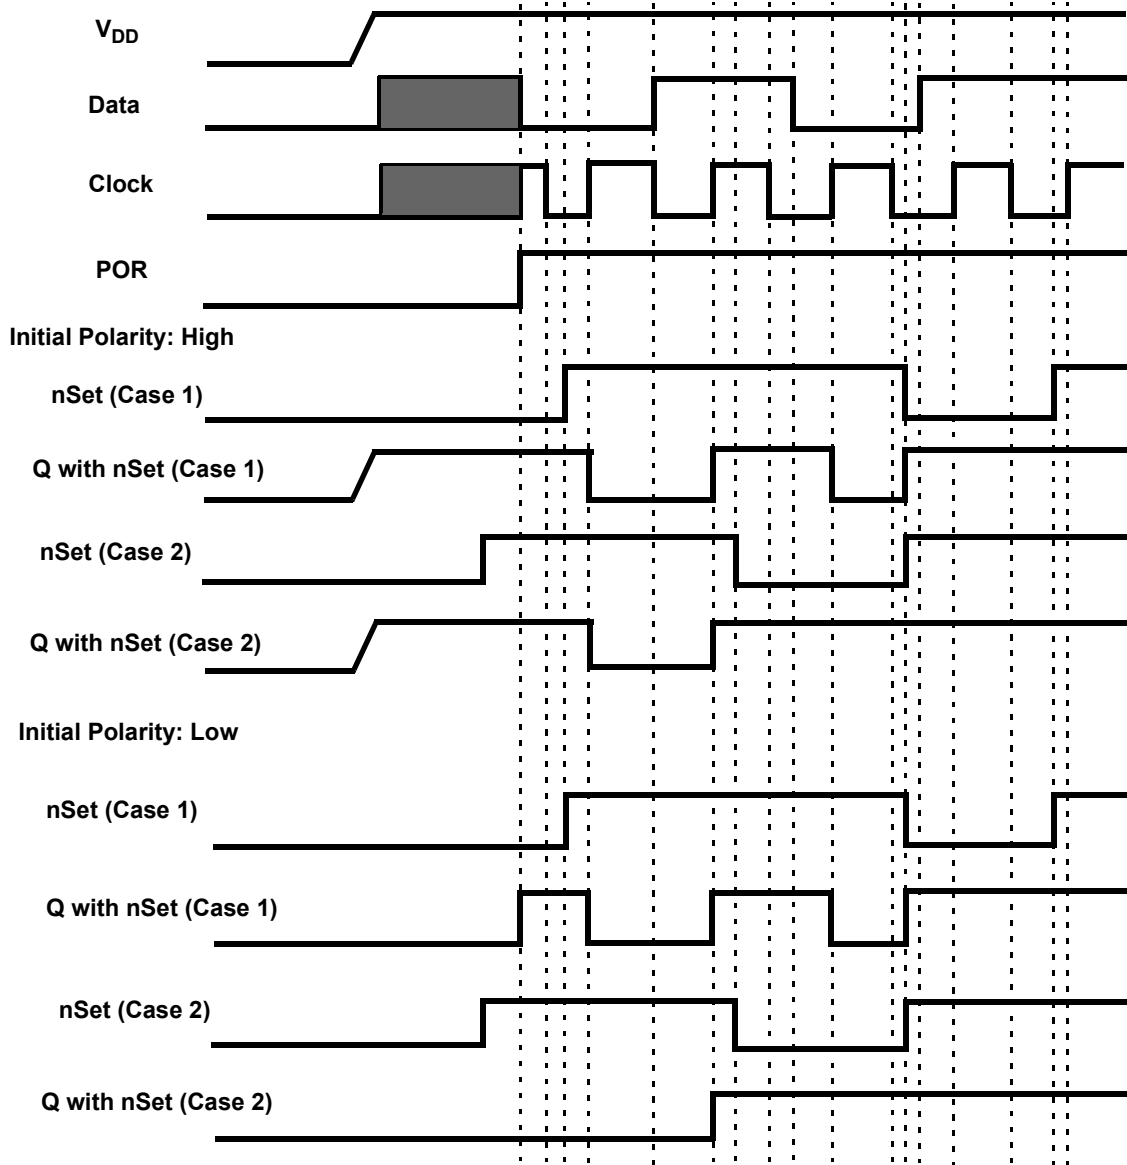

Figure 41: DFF Polarity Operations with nSet

11.5 3-BIT LUT OR PIPE DELAY/RIPPLE COUNTER MACROCELL

There is one macrocell that can serve as either a 3-bit LUT or as a Pipe Delay/Ripple Counter.

When used to implement LUT functions, the 3-bit LUT takes in three input signals from the connection matrix and produces a single output, which goes back into the connection matrix.

When used as a Pipe Delay, there are three inputs signals from the matrix, Input (IN), Clock (CLK), and Reset (nRST). The Pipe Delay cell is built from 16 D Flip-Flop logic cells that provide the three delay options, two of which are user selectable. The DFF cells are tied in series where the output (Q) of each delay cell goes to the next DFF cell input (IN). Both of the two outputs (OUT0 and OUT1) provide user selectable options for 1 - 16 stages of delay. There are delay output points for each set of the OUT0 and OUT1 outputs to a 4-input mux that is controlled by registers [1203:1200] for OUT0 and registers [1207:1204] for OUT1. The 4-input mux is used to control the selection of the amount of delay.

The overall time of the delay is based on the clock used in the SLG47105 design. Each DFF cell has a time delay of the inverse of the clock time (either external clock or the internal Oscillator within the SLG47105). The sum of the number of DFF cells used will be the total time delay of the Pipe Delay logic cell. OUT1 Output can be inverted (as selected by register [1197]).

In the Ripple Counter mode, there are 3 options for setting which use 7 bits. There are 3 bits to set nSET value (SV) in the range from 0 to 7. This value will be set into the Ripple Counter outputs when nSET input goes LOW. End value (EV) will use 3 bits for setting output code, which will be last code in the cycle. After reaching the EV, the Ripple Counter goes to the first code by the rising edge on CLK input. The Functionality mode option uses 1 bit. This setting defines how exactly Ripple Counter will operate.

The user can select one of the functionality modes by the register: RANGE or FULL. If the RANGE option is selected, the count starts from SV. If UP input is LOW the count goes down: $SV \rightarrow EV \rightarrow EV-1$ to $SV+1 \rightarrow SV$, and others (if SV is smaller than EV), or $SV \rightarrow SV-1$ to $EV+1 \rightarrow EV \rightarrow SV$ (if SV is bigger than EV). If UP input is HIGH, the count starts from SV up to EV, and others.

In the FULL range configuration, the Ripple Counter functions as follows. If UP input is LOW, the count starts from SV and goes down to 0. The current counter value jumps to EV and goes down to 0, and others.

If UP input is HIGH, the count goes up starting from SV. The current counter value jumps to 0 and counts up to EV, and others. See Ripple Counter functionality example in [Figure 43](#).

Every step is executed by the rising edge on CLK input.

Figure 42: 3-bit LUT6/Pipe Delay/Ripple Counter

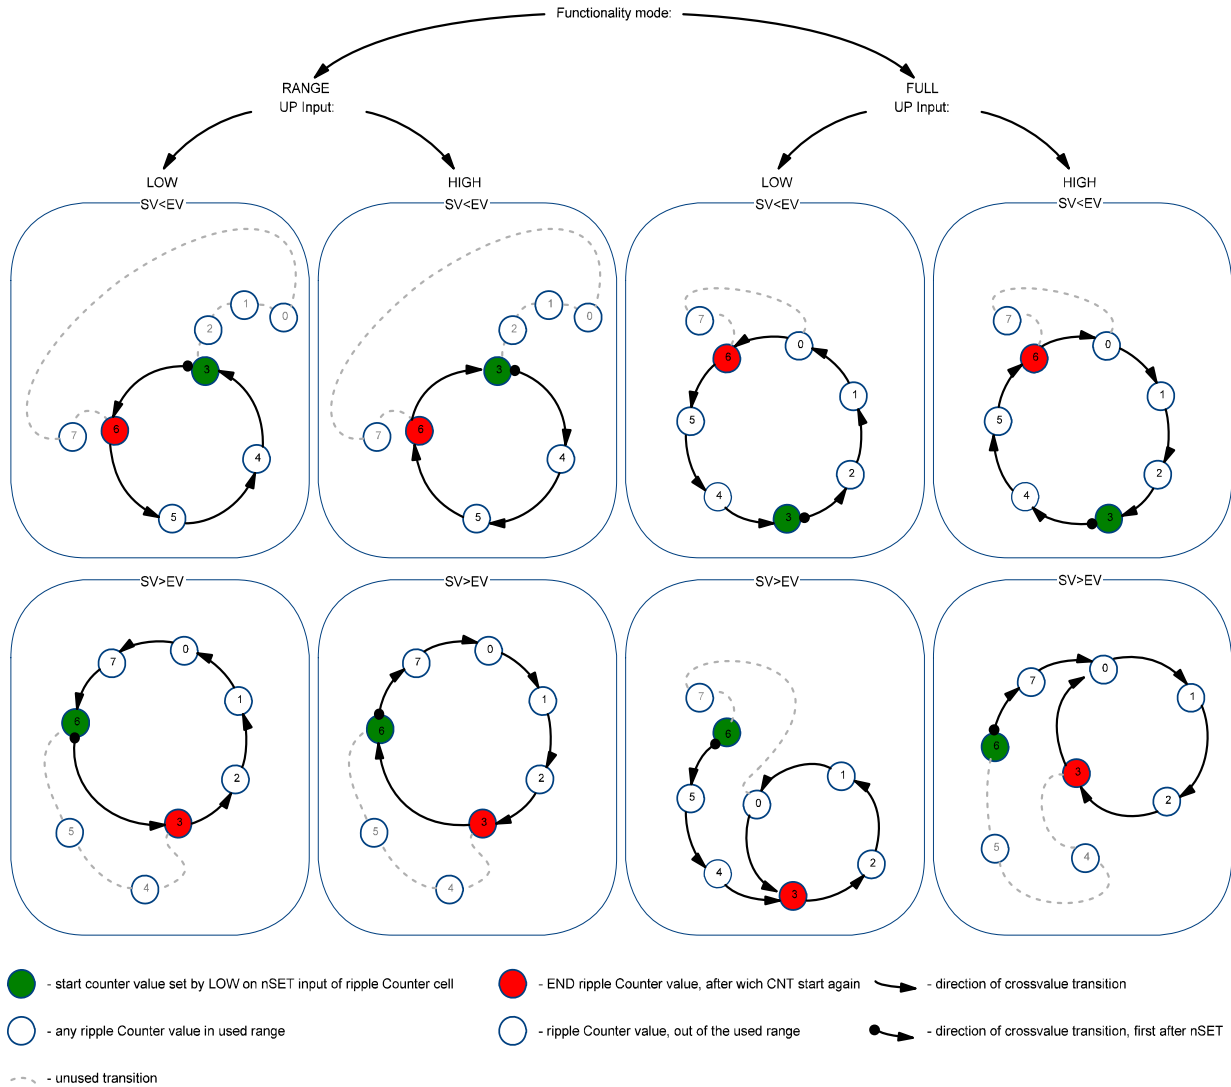

Figure 43: Example of Ripple Counter Functionality

11.5.1 3-bit LUT or Pipe Delay Macrocells Used as 3-bit LUT

Table 50: 3-bit LUT6 Truth Table

IN2	IN1	IN0	OUT	
0	0	0	register [1200]	LSB
0	0	1	register [1201]	
0	1	0	register [1202]	
0	1	1	register [1203]	
1	0	0	register [1204]	
1	0	1	register [1205]	
1	1	0	register [1206]	
1	1	1	register [1207]	MSB

Macrocell, when programmed for a LUT function, uses an 8-bit register to define their output function:

3-bit LUT6 is defined by registers [1207:1200]

11.6 4-BIT LUT OR D FLIP-FLOP MACROCELL

There is one macrocell that can serve as either 4-bit LUT or as D Flip-Flop. When used to implement LUT functions, the 4-bit LUT takes in two input signals from the connection matrix and produces a single output, which goes back into the connection matrix. When used to implement D Flip-Flop function, the two input signals from the connection matrix go to the data (D) and clock (CLK) inputs for the Flip-Flop, with the output going back to the connection matrix.

The operation of the D Flip-Flop and LATCH will follow the functional descriptions below:

DFF: CLK is rising edge triggered, then Q = D; otherwise Q will not change.

LATCH: when CLK is Low, then Q = D; otherwise Q remains its previous value (input D has no effect on the output when CLK is High).

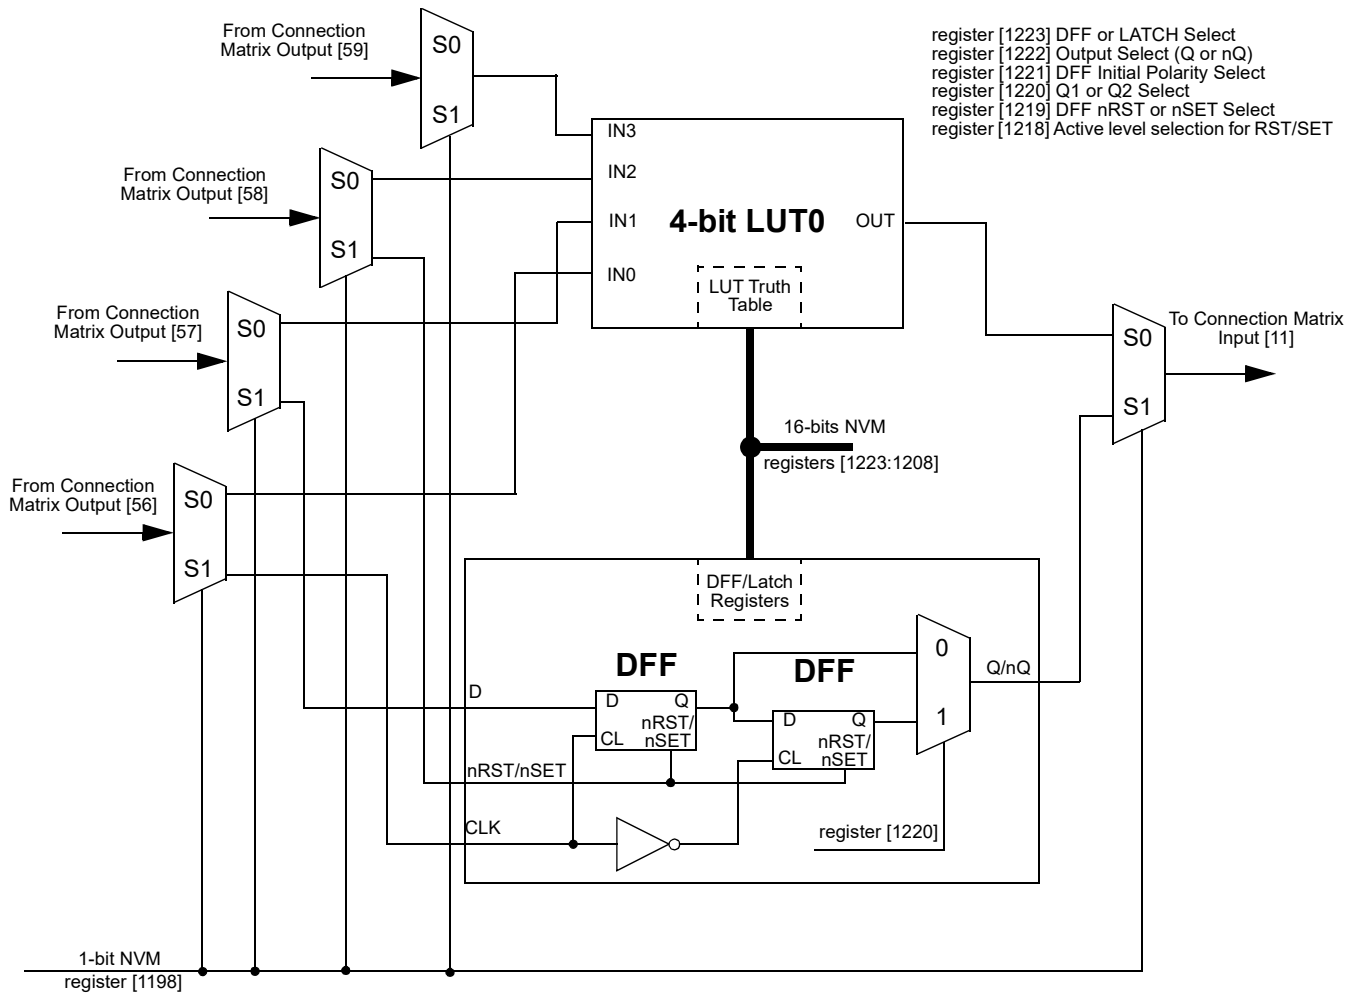

Figure 44: 4-bit LUT0 or DFF9

12 Multi-Function Macrocells

The SLG47105 has 5 Multi-Function macrocells that can serve as more than one logic or timing function. In each case, they can serve as a LUT, DFF with flexible settings, or as CNT/DLY with multiple modes such as One Shot, Frequency Detect, Edge Detect, and others. Also, the macrocell is capable to combine those functions: LUT/DFF connected to CNT/DLY or CNT/DLY connected to LUT/DFF, see [Figure 45](#).

See the list below for the functions that can be implemented in these macrocells:

- Four macrocells that can serve as 3-bit LUTs/D Flip-Flops and as 8-bit Counter/Delays
- One macrocell that can serve as a 4-bit LUT/D Flip-Flop and as 16-bit Counter/Delay/FSM

Figure 45: Possible Connections Inside Multi-Function Macrocell

Inputs/Outputs for the 5 Multi-Function macrocells are configured from the connection matrix with specific logic functions being defined by the state of NVM bits.

When used as a LUT to implement combinatorial logic functions, the outputs of the LUTs can be configured to any user defined function, including the following standard digital logic devices (AND, NAND, OR, NOR, XOR, XNOR).

12.1 3-BIT LUT OR DFF/LATCH WITH 8-BIT COUNTER/DELAY MACROCELLS

There are four macrocells that can serve as 3-bit LUTs/D Flip-Flops and as 8-bit Counter/Delays.

When used to implement LUT functions, the 3-bit LUTs each takes in three input signals from the connection matrix and produces a single output, which goes back into the connection matrix or can be connected to CNT/DLY's input.

When used to implement D Flip-Flop function, the three input signals from the connection matrix go to the data (D), clock (CLK), and Reset/Set (nRST/nSET) inputs of the Flip-Flop, with the output going back to the connection matrix or to the CNT/DLY's input.

When used to implement Counter/Delays, each macrocell has a dedicated matrix input connection. For flexibility, each of these macrocells has a large selection of internal and external clock sources, as well as the option to chain from the output of the previous (N-1) CNT/DLY macrocell, to implement longer count/delay circuits. These macrocells can also operate in a One-Shot mode, which will generate an output pulse of user-defined width. They can also operate in a Frequency Detection or Edge Detection mode.

Counter/Delay macrocell has an initial value, which defines its initial value after GPAK is powered up. It is possible to select initial Low or initial High, as well as the initial value defined by a Delay In signal.

For example, in case the initial LOW option is used, the rising edge delay will start operation.

For timing diagrams refer to Section 12.3.

Only CNT0 and CNT4 active count value can be read via I²C. However, it is possible to change the counter value for any macrocell using I²C write commands. In this mode, it is possible to load count data immediately (plus two clock cycles) or after counter ends counting. See Section 21.5.4 for further details.

Note: After two DFF – counters initialize with counter data = 0 after POR.

Initial state = 1 – counters initialize with counter data = 0 after POR.

Initial state = 0 And After two DFF is bypass – counters initialize with counter data after POR.

12.1.1 3-bit LUT or 8-bit CNT/DLY Block Diagrams

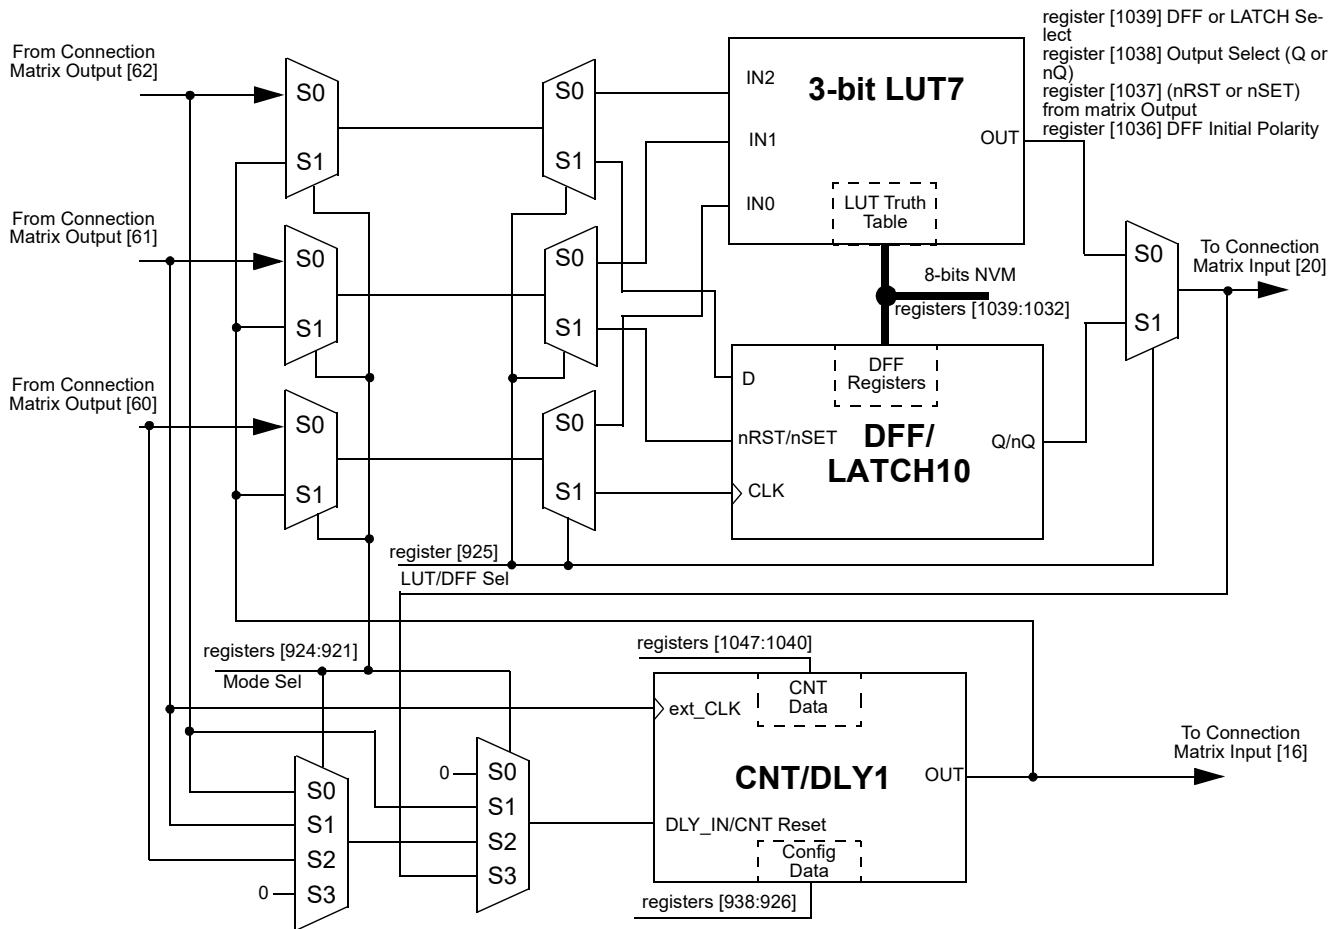

Figure 46: 8-bit Multi-Function Macrocells Block Diagram (3-bit LUT7/DFF10, CNT/DLY1)

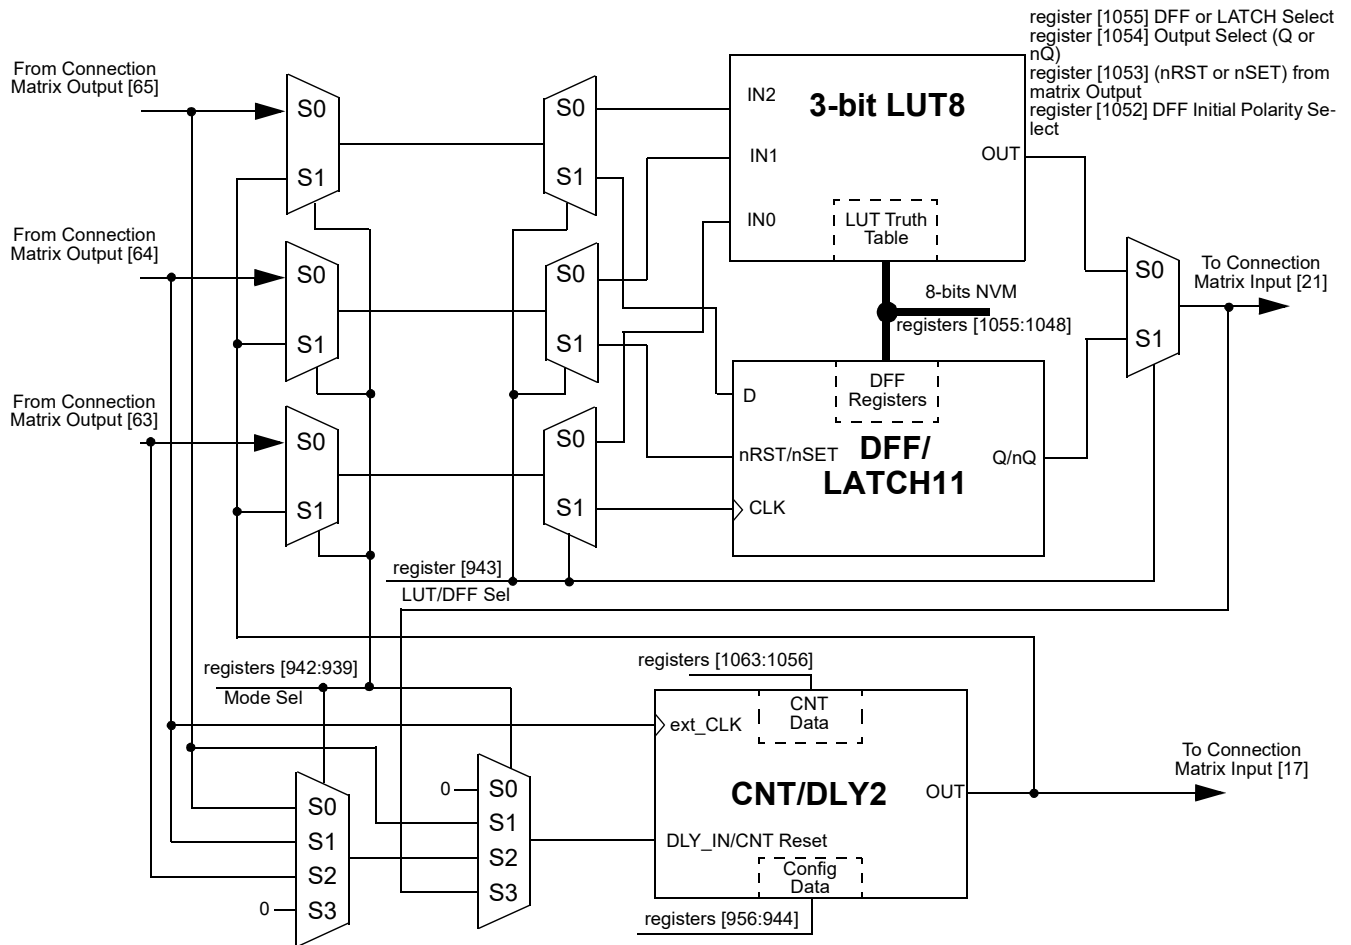

Figure 47: 8-bit Multi-Function Macrocells Block Diagram (3-bit LUT8/DFF11, CNT/DLY2)

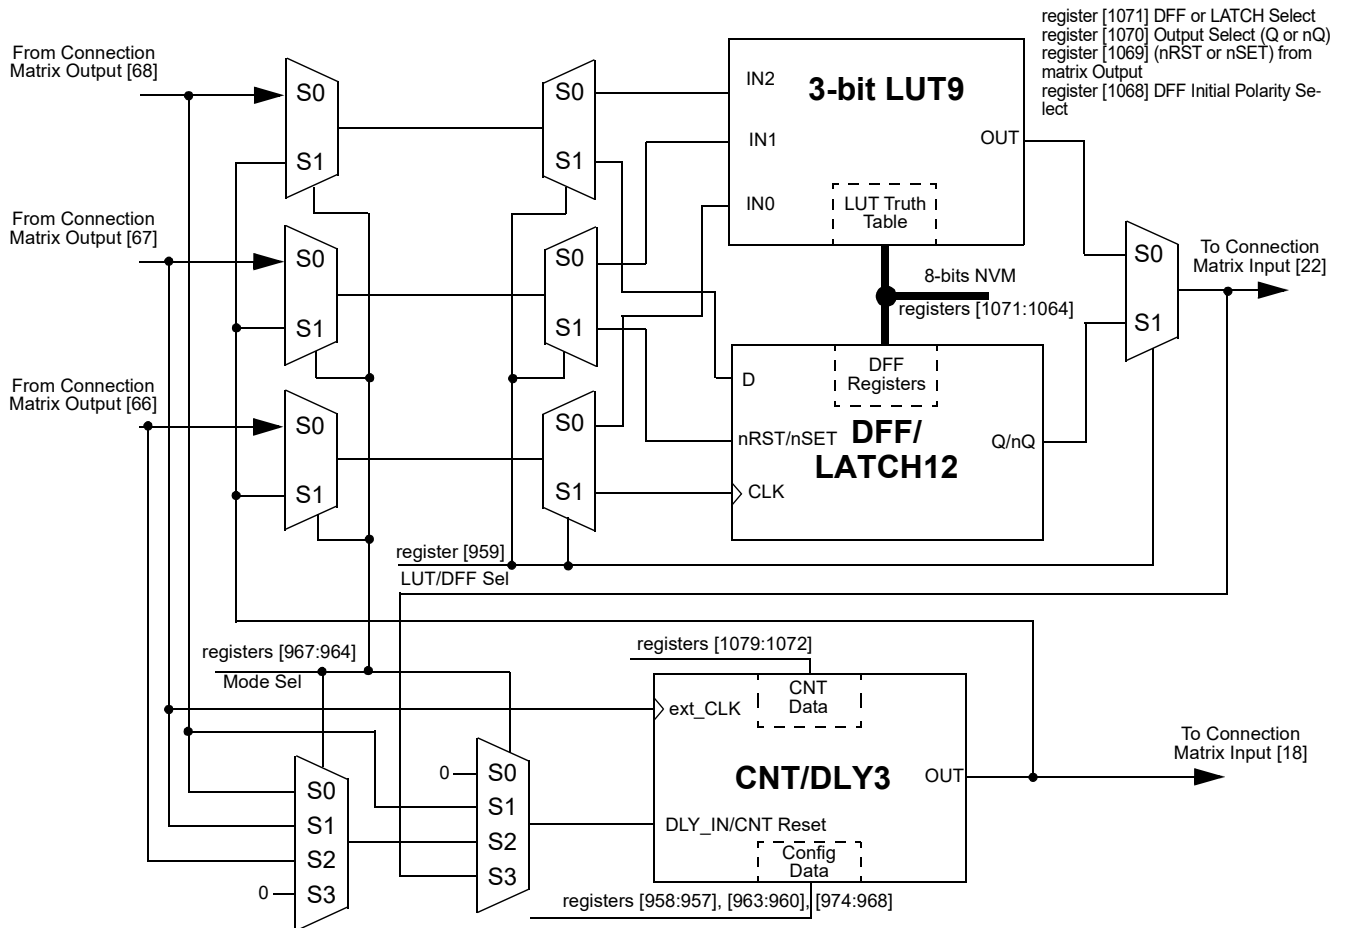

Figure 48: 8-bit Multi-Function Macrocells Block Diagram (3-bit LUT9/DFF12, CNT/DLY3)

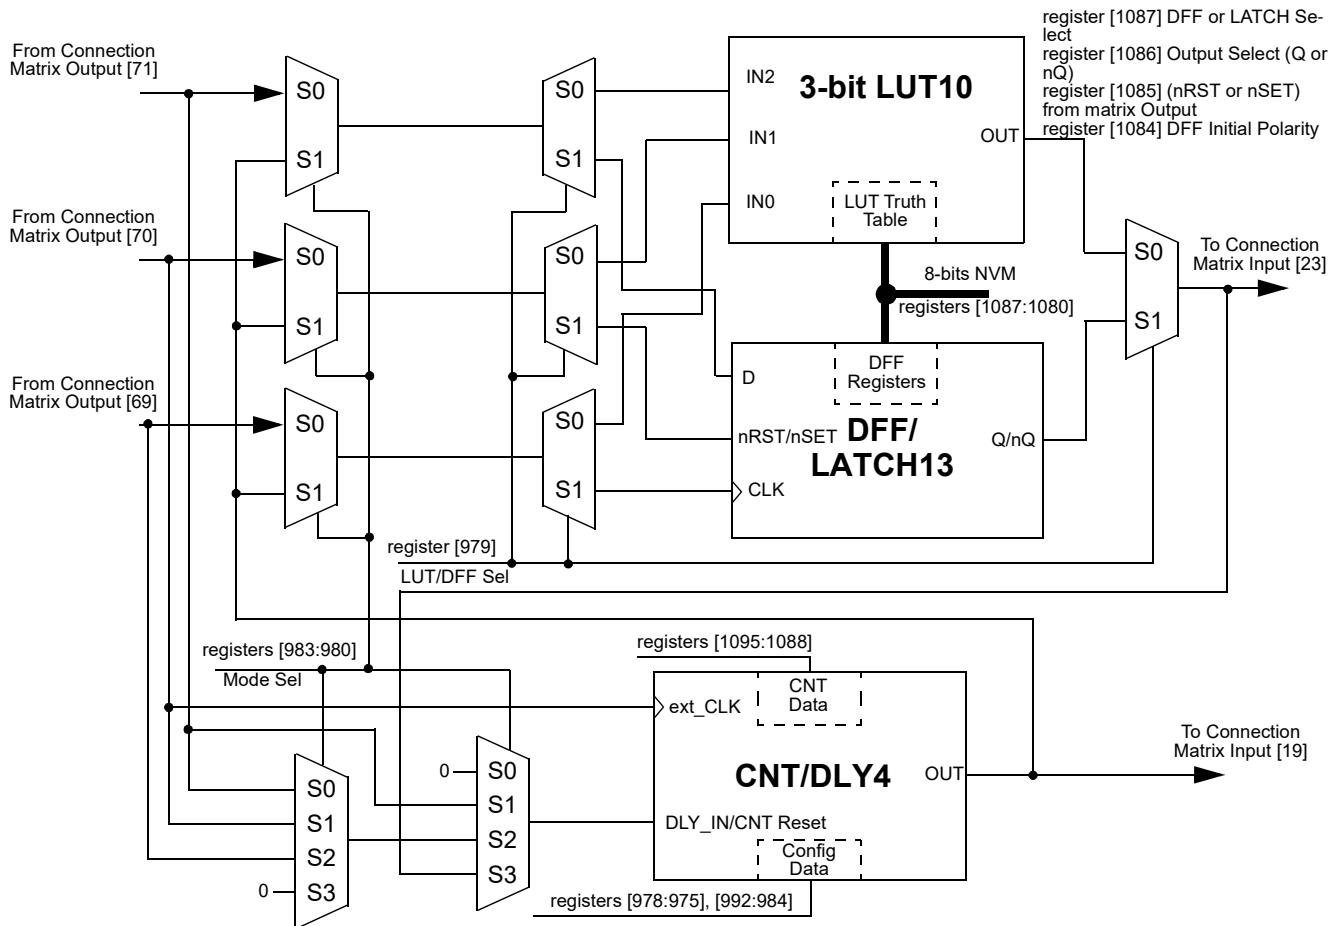

Figure 49: 8-bit Multi-Function Macrocells Block Diagram (3-bit LUT10/DFF13, CNT/DLY4)

There is a possibility to use LUT/DFF and CNT/DLY simultaneously.

Note: It is not possible to use LUT and DFF at once, one of these macrocells must be selected.

- Case 1. LUT/DFF in front of CNT/DLY. Three input signals from the connection matrix go to previously selected LUT or DFF's inputs and produce a single output which goes to a CNT/DLY input. In its turn Counter/Delay's output goes back to the matrix.
- Case 2. CNT/DLY in front of LUT/DFF. Two input signals from the connection matrix go to CNT/DLY's inputs (IN and CLK). Its output signal can be connected to any input of previously selected LUT or DFF, after which the signal goes back to the matrix.
- Case 3. Single LUT/DFF or CNT/DLY. Also, it is possible to use a standalone LUT/DFF or CNT/DLY. In this case, all inputs and output of the macrocell are connected to the matrix.

12.1.2 3-bit LUT or CNT/DLYs Used as 3-bit LUTs

Table 53: 3-bit LUT7 Truth Table

1	0	1	register [1085]	
1	1	0	register [1086]	
1	1	1	register [1087]	MSB

Each macrocell, when programmed for a LUT function, uses a 8-bit register to define their output function:

3-bit LUT7 is defined by registers [1039:1032]

3-bit LUT8 is defined by registers [1055:1048]

3-bit LUT9 is defined by registers [1071:1064]

3-bit LUT10 is defined by registers [1087:1080]

12.2 4-BIT LUT OR DFF/LATCH WITH 16-BIT COUNTER/DELAY MACROCELL

There is one macrocell that can serve as either 4-bit LUT or as 16-bit Counter/Delay. When used to implement LUT function, the 4-bit LUT takes in four input signals from the Connection Matrix and produces a single output, which goes back into the Connection Matrix. When used to implement 16-bit Counter/Delay function, two of four input signals from the connection matrix go to the external clock (EXT_CLK) and reset (DLY_IN/CNT Reset) for the Counter/Delay, with the output going back to the connection matrix.

This macrocell has an optional Finite State Machine (FSM) function. There are two additional matrix inputs for Up and Keep to support FSM functionality.

This macrocell can also operate in a one-shot mode, which will generate an output pulse of user-defined width.

This macrocell can also operate in a frequency detection or edge detection mode.

This macrocell can have its active count value read via I²C. See Section 21.5.4 for further details.

Note: After two DFF – counters initialize with counter data = 0 after POR.

Initial state = 1 – counters initialize with counter data = 0 after POR.

Initial state = 0 And After two DFF is bypass – counters initialize with counter data after POR.

12.2.1 4-bit LUT or DFF/LATCH with 16-bit CNT/DLY Block Diagram

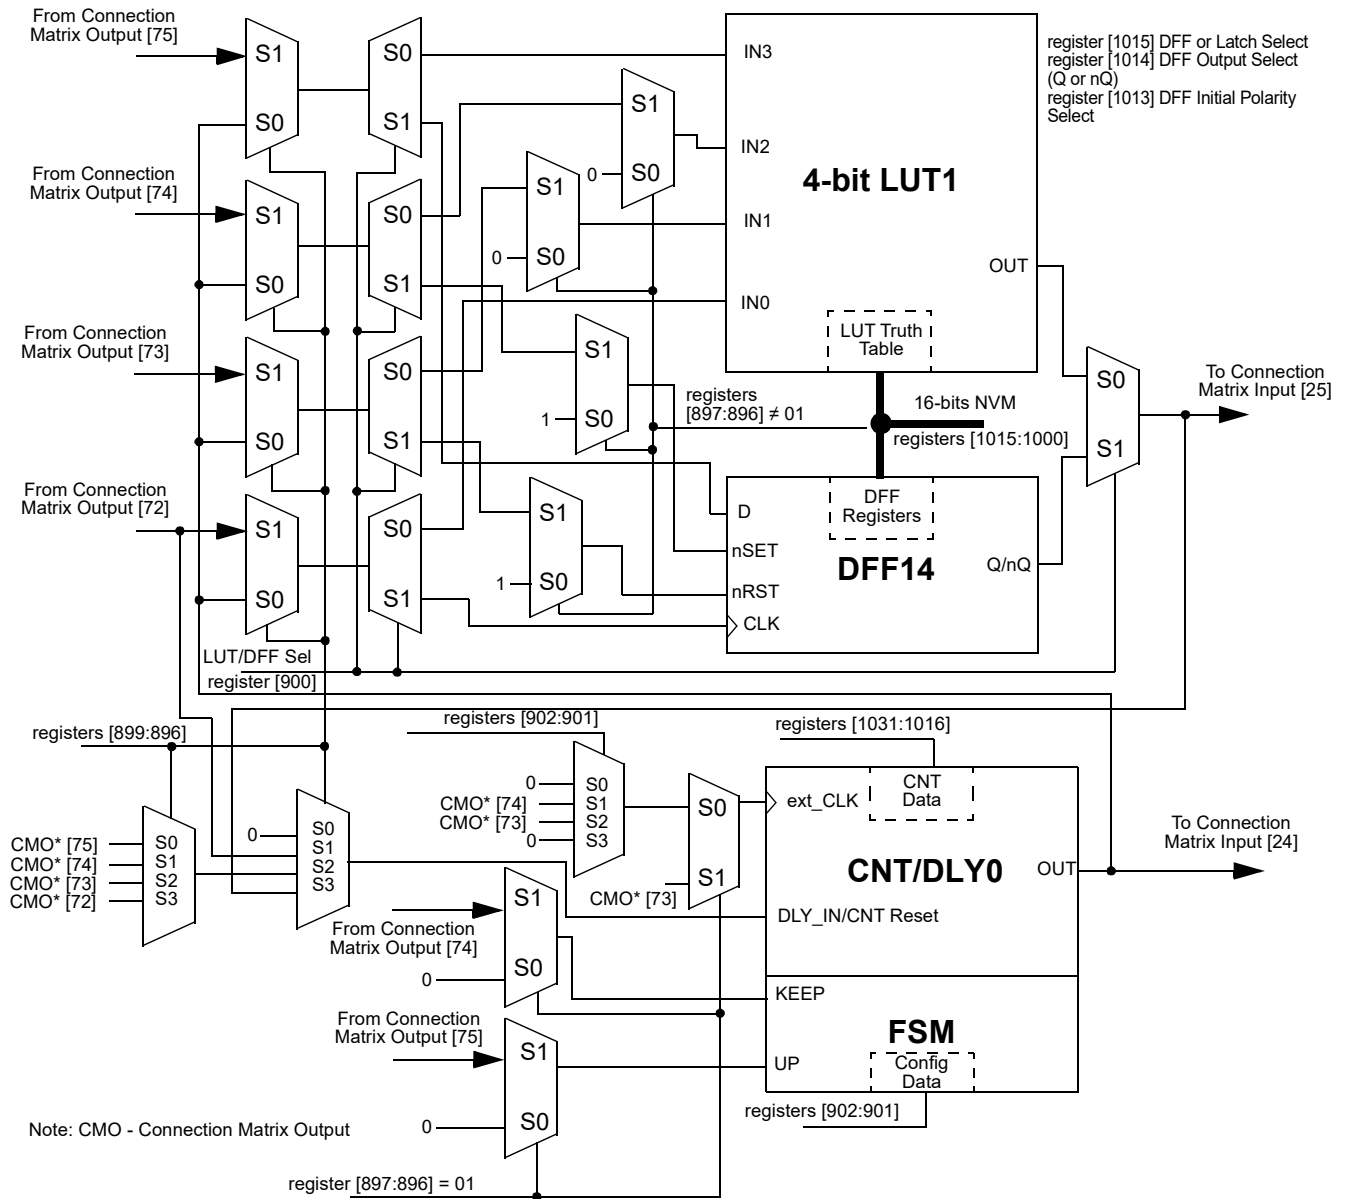

Figure 50: 16-bit Multi-Function Macrocell Block Diagram (4-bit LUT1/DFF14, CNT/DLY/FSM0)

12.3 CNT/DLY/FSM TIMING DIAGRAMS

12.3.1 Delay Mode CNT/DLY0 to CNT/DLY4

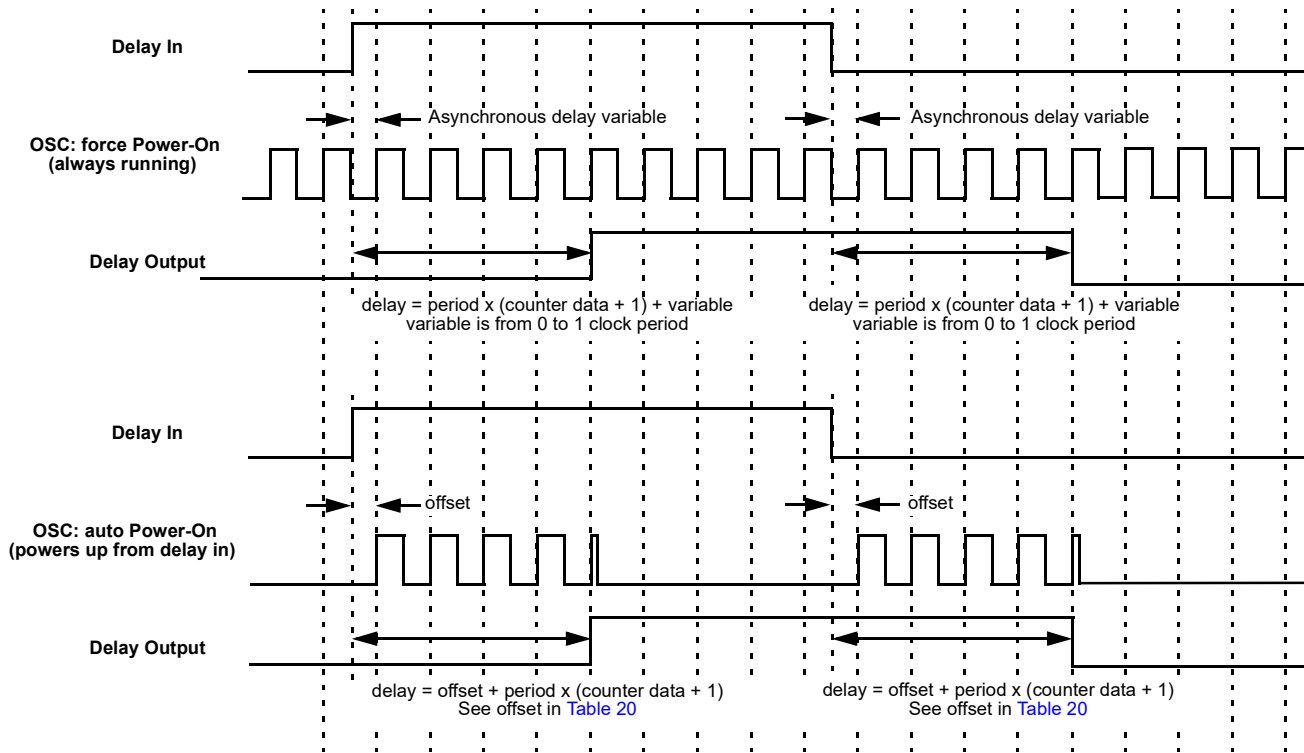

Figure 51: Delay Mode Timing Diagram, Edge Select: Both, Counter Data: 3

The macrocell shifts the respective edge to a set time and restarts by appropriate edge. It works as a filter if the input signal is shorter than the delay time.

Figure 52: Delay Mode Timing Diagram for Different Edge Select Modes

12.3.2 Count Mode (Count Data: 3), Counter Reset (Rising Edge Detect) CNT/DLY0 to CNT/DLY4

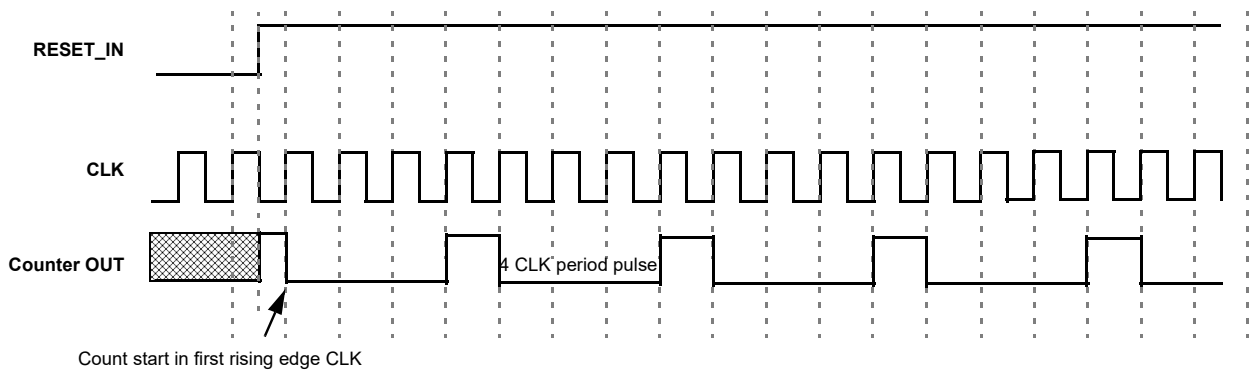

Figure 53: Counter Mode Timing Diagram without Two DFFs Synced Up

Note 1 This mode may cause counter data to be loaded wrong, if reset releases at the same time when the clock appears. As a solution please use the mode with two DFFs synced up.

Figure 54: Counter Mode Timing Diagram with Two DFFs Synced Up

12.3.3 One-shot Mode CNT/DLY0 to CNT/DLY4

This macrocell will generate a pulse whenever a selected edge is detected on its input. Register bits set the edge selection. The pulse width is determined by counter data and clock selection properties.

The output pulse polarity (non-inverted or inverted) is selected by register bit. Any incoming edges will be ignored during the pulse width generation. The following diagram shows one-shot function for non-inverted output.

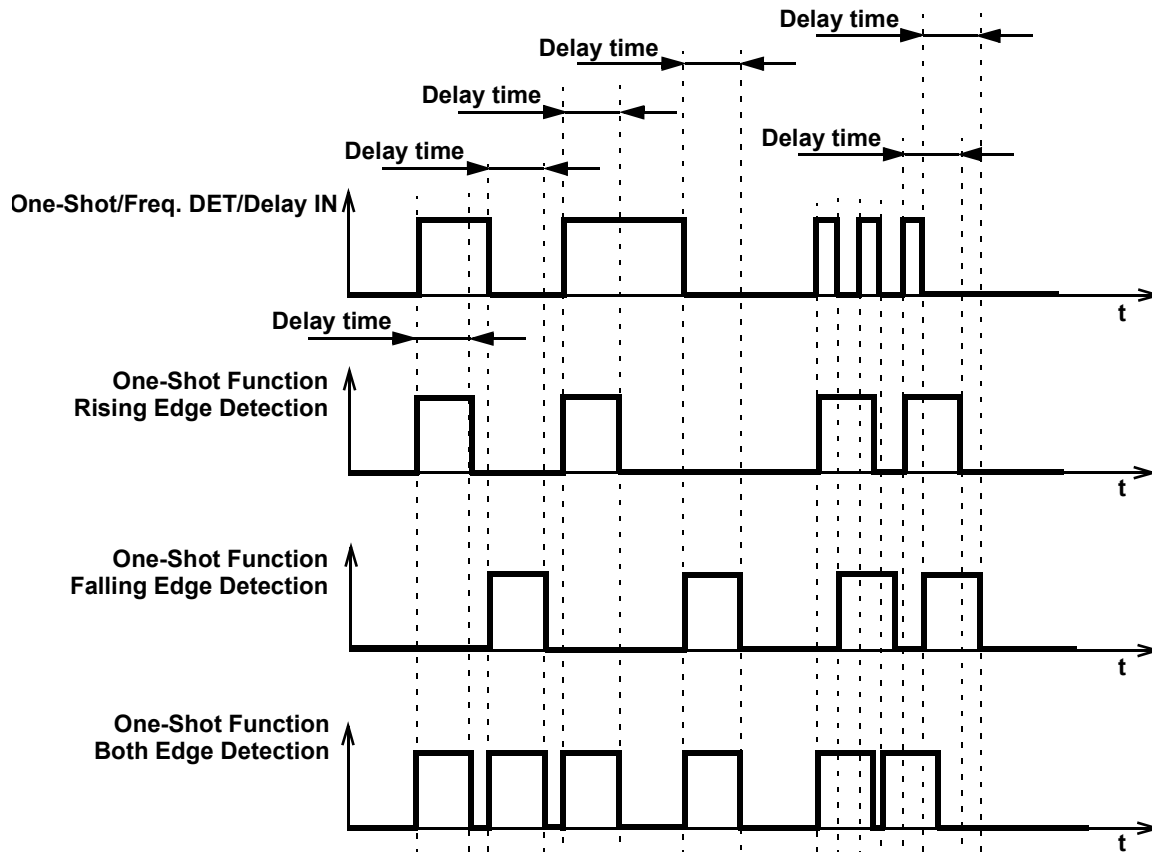

Figure 55: One-Shot Function Timing Diagram

This macrocell generates a high level pulse with a set width (defined by counter data) when detecting the respective edge. It does not restart while pulse is high.

12.3.4 Frequency Detection Mode CNT/DLY0 to CNT/DLY4

Rising Edge: The output goes high if the time between two successive edges is less than the delay. The output goes low if the second rising edge has not come after the last rising edge in specified time.

Falling Edge: The output goes high if the time between two falling edges is less than the set time. The output goes low if the second falling edge has not come after the last falling edge in specified time.

Both Edge: The output goes high if the time between the rising and falling edges is less than the set time, which is equivalent to the length of the pulse. The output goes low if after the last rising/falling edge and specified time, the second edge has not come.

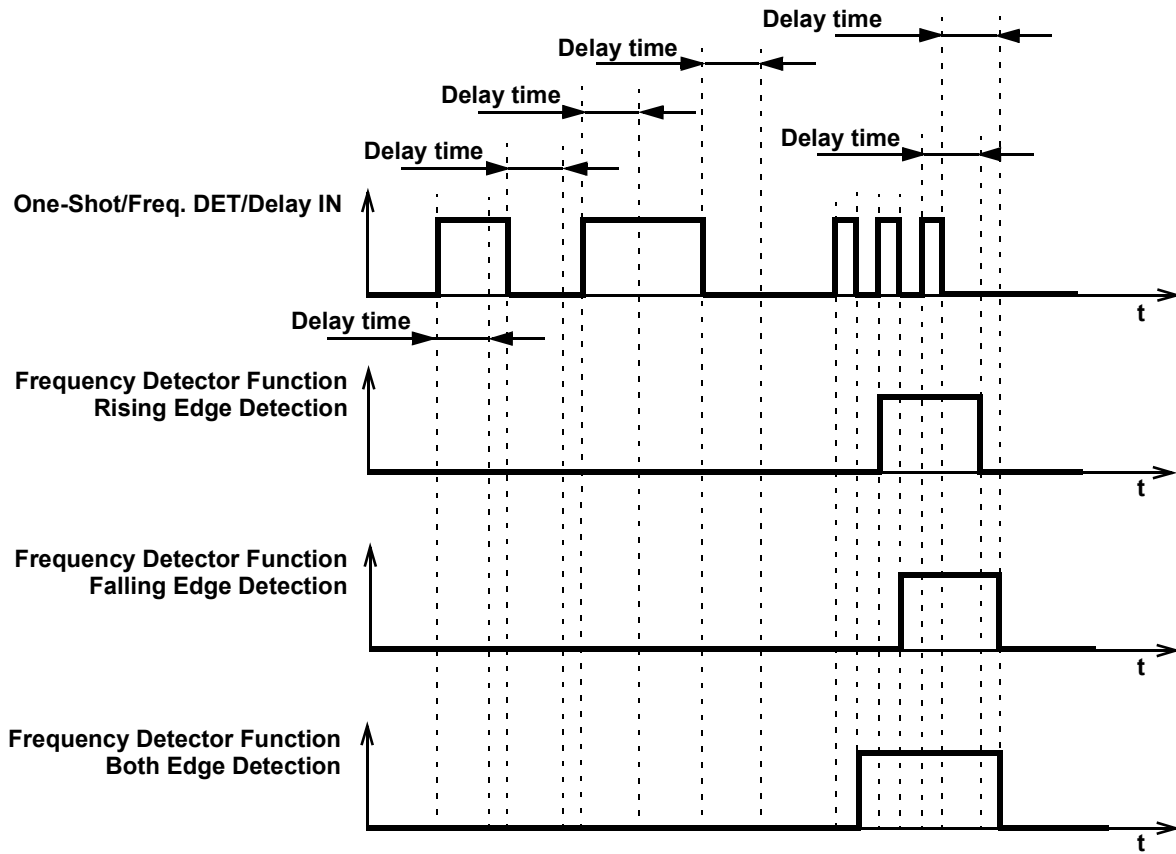

Figure 56: Frequency Detection Mode Timing Diagram

12.3.5 Edge Detection Mode CNT/DLY1 to CNT/DLY4

The macrocell generates high level short pulse when detecting the respective edge.

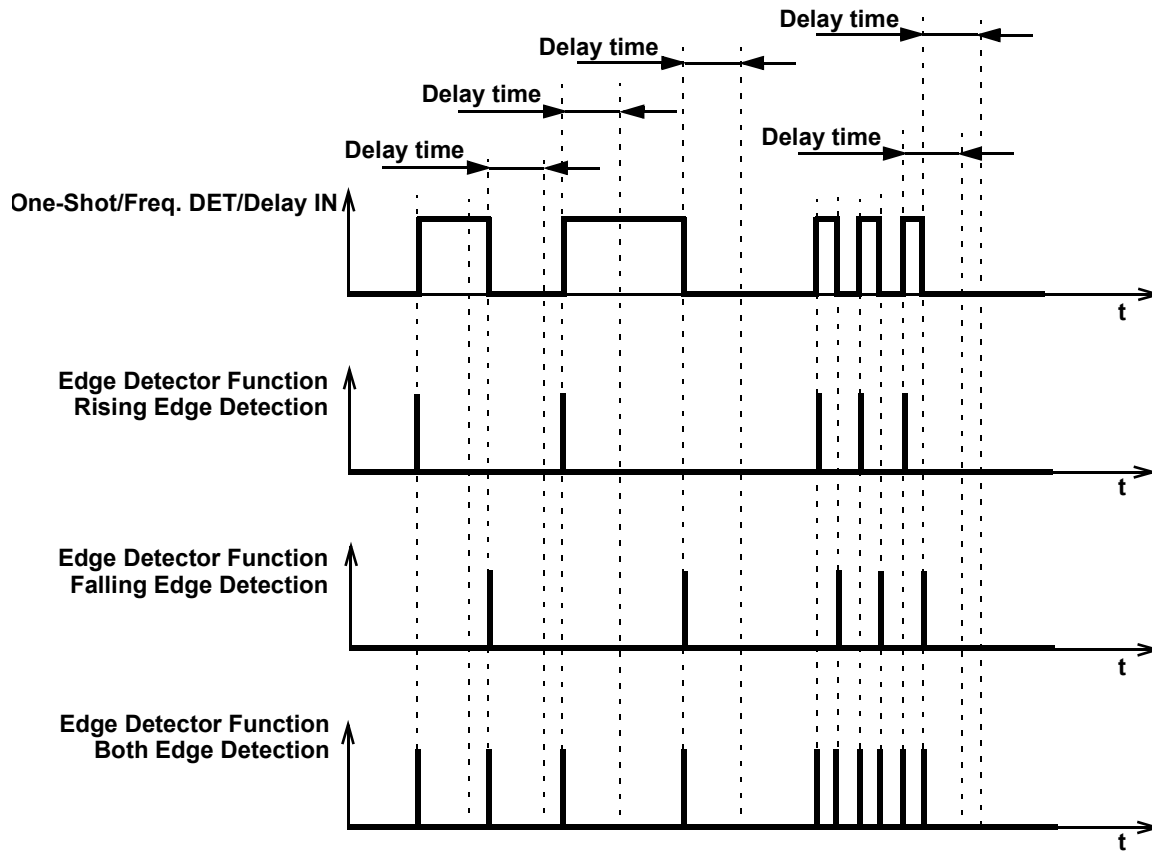

Figure 57: Edge Detection Mode Timing Diagram

12.3.6 Delayed Edge Detection Mode CNT/DLY0 to CNT/DLY4

In Delayed Edge Detection Mode, High level short pulses are generated on the macrocell output after the configured delay time, if the corresponding edge was detected on the input.

If the input signal is changed during the set delay time, the pulse will not be generated. See Figure 58.

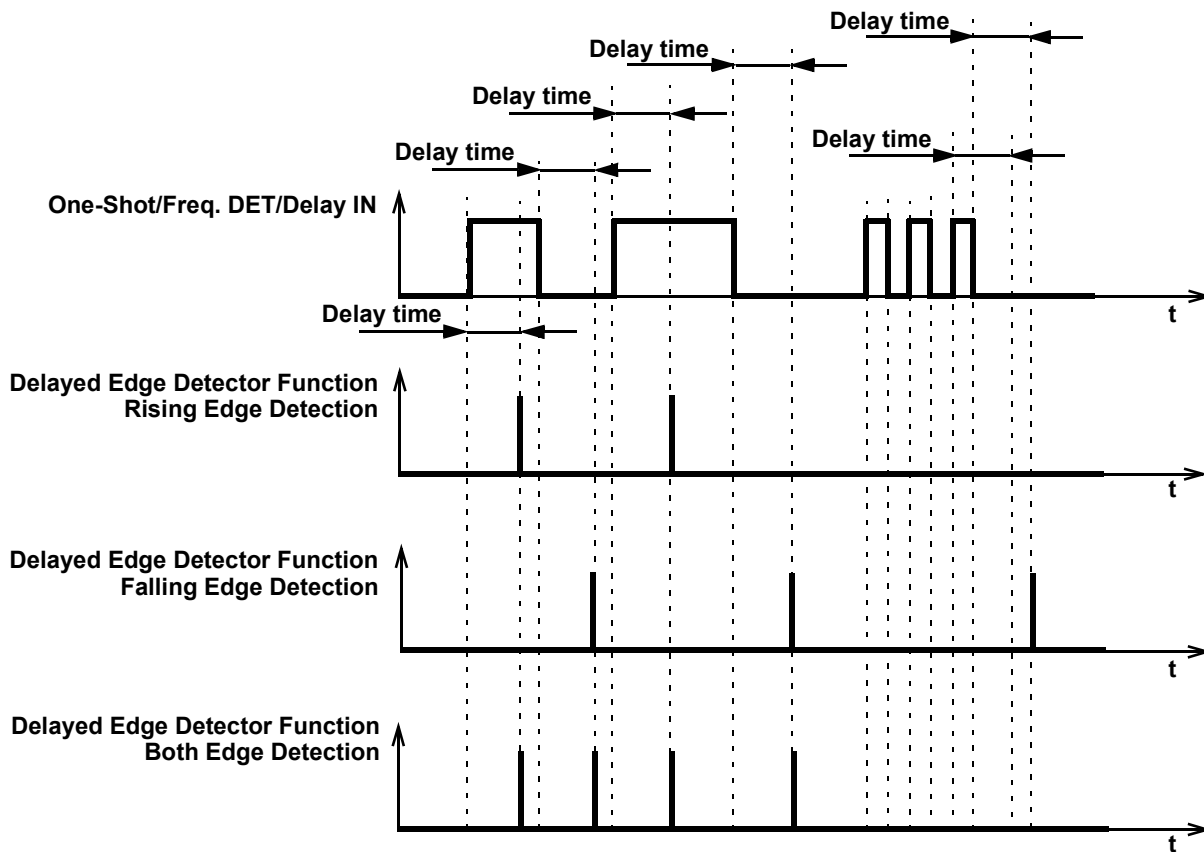

Figure 58: Delayed Edge Detection Mode Timing Diagram

12.3.7 CNT/FSM Mode CNT/DLY0

Figure 59: CNT/FSM Timing Diagram (Reset Rising Edge Mode, Oscillator is Forced On, UP = 0) for Counter Data = 3

Figure 60: CNT/FSM Timing Diagram (Set Rising Edge Mode, Oscillator is Forced On, UP = 0) for Counter Data = 3

Figure 61: CNT/FSM Timing Diagram (Reset Rising Edge Mode, Oscillator is Forced On, UP = 1) for Counter Data = 3

Figure 62: CNT/FSM Timing Diagram (Set Rising Edge Mode, Oscillator is Forced On, UP = 1) for Counter Data = 3

12.3.8 The Difference in Counter Value for Counter, Delay, One-Shot, and Frequency Detect Modes

There is a difference in counter value for Counter and Delay/One-Shot/Frequency Detect modes. Compared to Counter mode, in Delay/One-Shot/Frequency Detect modes the counter value is shifted for two rising edges of the clock signal.

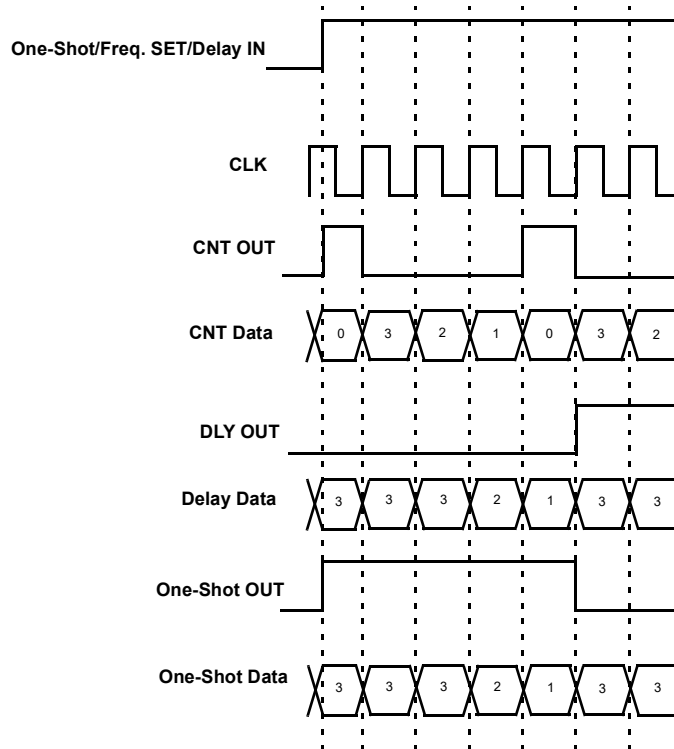

Figure 63: Counter Value, Counter Data = 3

12.4 WAKE AND SLEEP CONTROLLER

SLG47105 has a Wake and Sleep function for two General Purpose ACMPs. The macrocell CNT/DLY0 can be reconfigured for this purpose by setting register [918] = 1 and registers [904:903] = 11. The WS serves for power saving, it allows to switch on and off selected General Purpose ACMPs on a selected bit of 16-bit counter.

Note 1 BG/Analog_Good time is long and should be considered in the wake and sleep timing in case it dynamically powers on/off.
Note 2 Wake time should be long enough to make sure ACMP and Vref have enough time to get a sample before going to sleep.

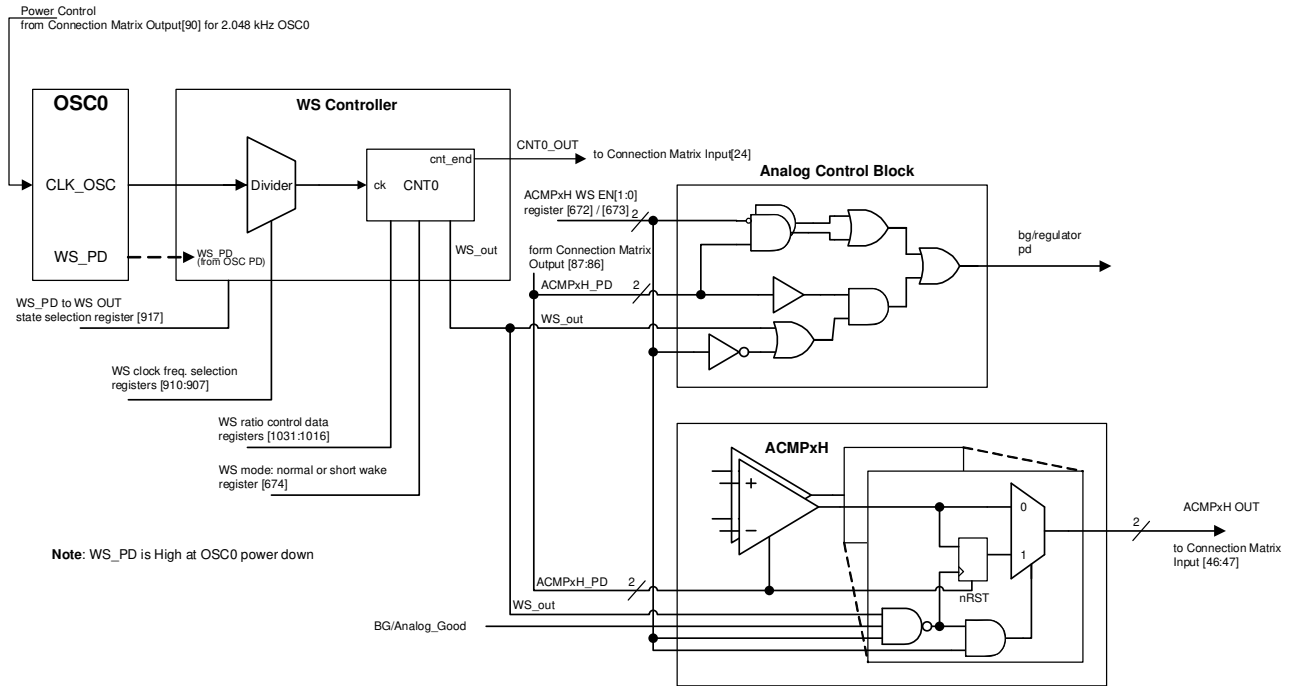

Figure 64: Wake/Sleep Controller

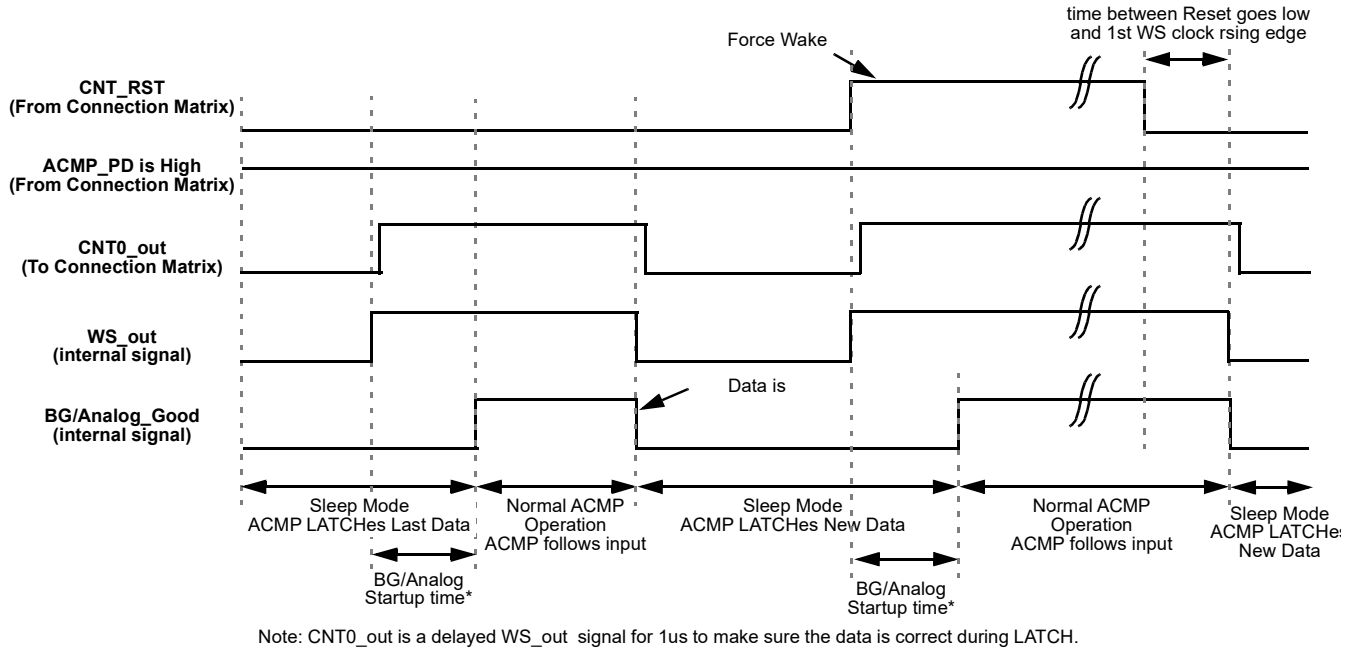

Figure 65: Wake/Sleep Timing Diagram, Normal Wake Mode, Counter Reset is Used

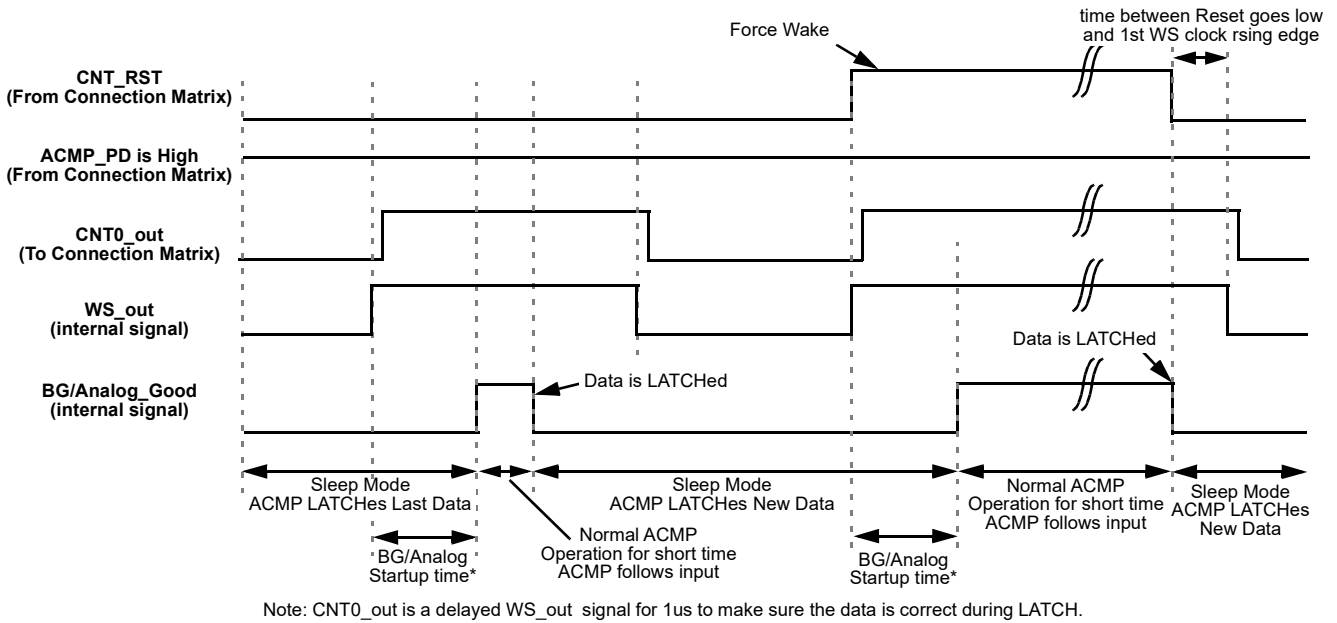

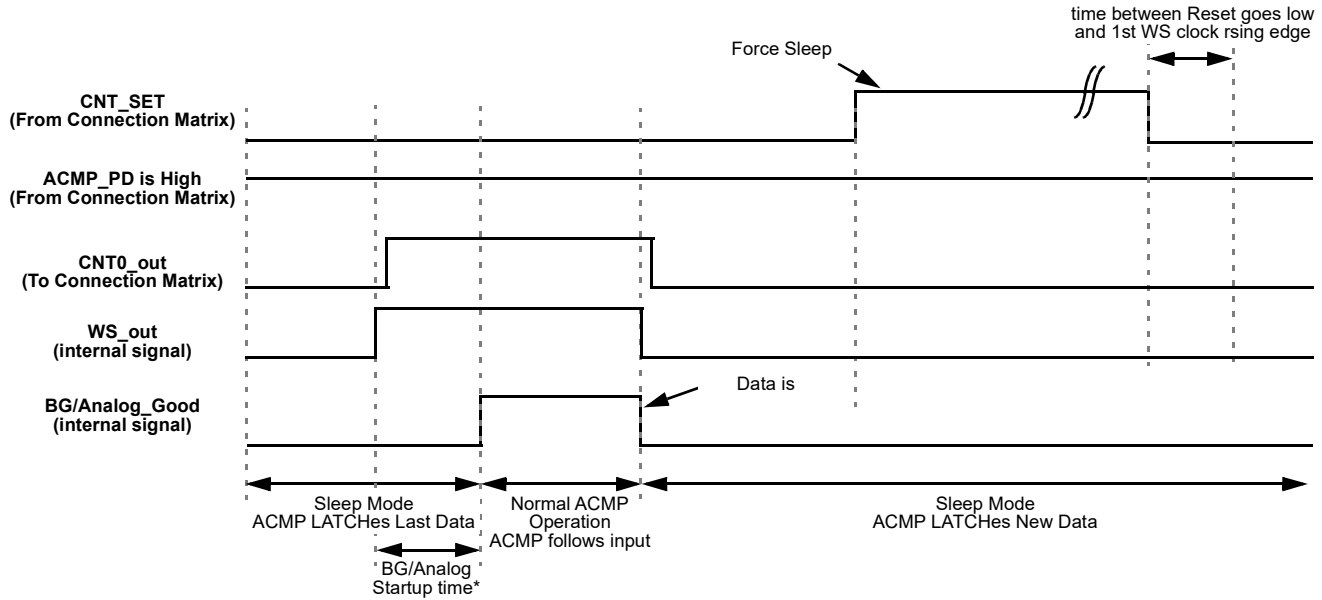

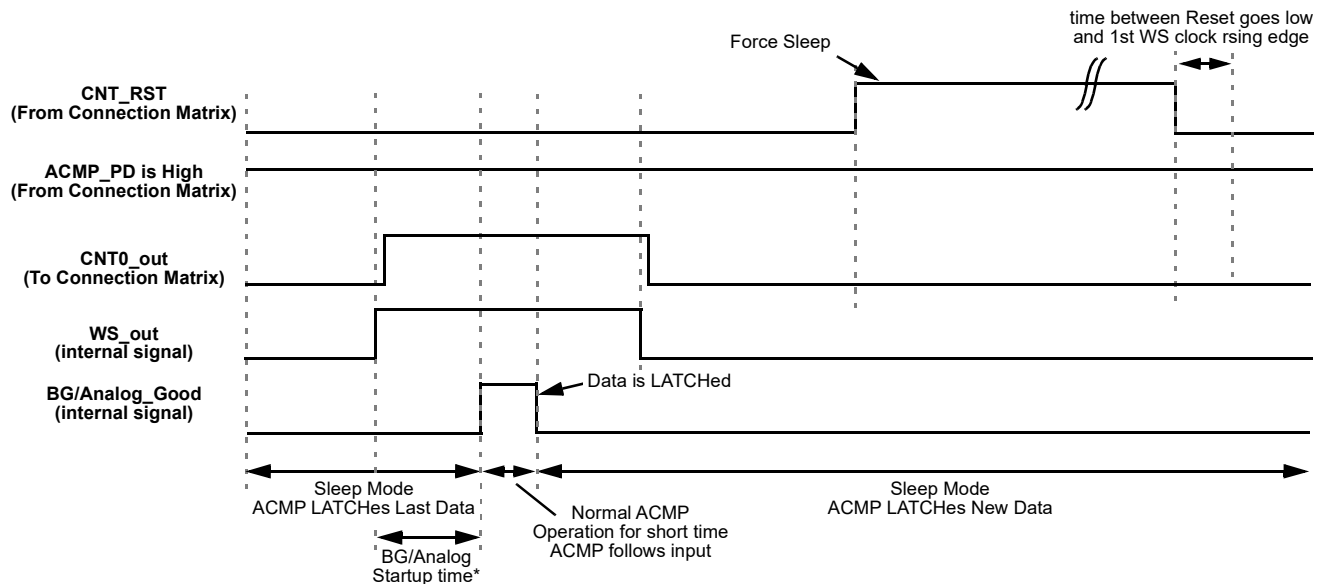

Figure 66: Wake/Sleep Timing Diagram, Short Wake Mode, Counter Reset is Used

Note: CNT0_out is a delayed WS_out signal for 1us to make sure the data is correct during LATCH.

Figure 67: Wake/Sleep Timing Diagram, Normal Wake Mode, Counter Set is Used

Note: CNT0_out is a delayed WS_out signal for 1us to make sure the data is correct during LATCH.

Figure 68: Wake/Sleep Timing Diagram, Short Wake Mode, Counter Set is Used

Note: If low power BG is powered on/off by WS, the wake time should be longer than 2.1 ms. The BG/analog startup time will take maximal 2 ms. Therefore, 8 periods of the Oscillator0 is recommended for the wake time, when BG is configured to Auto Power mode. If low power BG is always on, Oscillator0 period is longer than required wake time. The short wake mode can be used to reduce the current consumption. The short wake mode is edge triggered when the wake signal is latched by a rising edge

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

and released the Power-On signal after the ACMP output data is latched. This allows to have a valid ACMP data for any type of wake signal and have the optimized current consumption.

To use any ACMP under WS controller, the following settings must be done:

- ACMP Power Up Input from matrix = 1 (for each ACMP separately);
- CNT/DLY0 must be set to Wake and Sleep Controller function (for all ACMP);
- Register WS → enable (for each ACMP separately);
- CNT/DLY0 set/reset input = 0 (for all ACMP).

As the OSC, any oscillator with any pre-divider can be used. The user can select a period of time while the ACMP is sleeping in a range of 1 - 65535 clock cycles. Before they are sent to sleep their outputs are latched, so the ACMPs remain their state (High or Low) while sleeping.

WS controller has the following settings:

- Wake and Sleep Output State (High/Low)
 - If OSC is powered off (Power-down option is selected; Power-down input = 1) and Wake and Sleep Output State = High, the ACMP is continuously on.
 - If OSC is powered off (Power-down option is selected; Power-down input = 1) and Wake and Sleep Output State = Low, the ACMP is continuously off.
 - Both cases WS function is turned off.

- Counter Data (Range: 1 - 65535)

The User can select wake and sleep ratio of the ACMP; counter data = sleep time, one clock = wake time.

- Q mode - defines the state of WS counter data when Set/Reset signal appears Reset - when active signal appears, the WS counter will reset to zero and High level signal on its output will turn on the ACMPs. When Reset signal goes out, the WS counter will go Low and turn off the ACMP until the counter counts up to the end. Set - when active signal appears, the WS counter will stop and Low level signal on its output will turn off the ACMP. When Set signal goes out, the WS counter will go on counting and High level signal will turn on the ACMP while counter is counting up to the end.

Note: The OSC0 matrix power down to control ACMP WS is not supported for short wait time option.

- Edge Select defines the edge for Q mode
 - High level Set/Reset - switches mode Set/Reset when level is High

Note: Q mode operates only in case of "High Level Set/Reset".

- Wake time selection - time required for wake signal to turn the ACMPxH on

Normal Wake Time - when WS signal is High, it takes BG/analog start up time to turn the ACMPs on. They will stay on until WS signal is Low again. Wake time is one clock period. It should be longer than BG turn on time and minimal required comparing time of the ACMP.

Short Wake Time - when WS signal is High, it takes BG/analog start up time to turn the ACMPs on. They will stay on for 1 μ s and turn off regardless of WS signal. The WS signal width does not matter.

- Keep - pauses counting while Keep = 1
- Up - reverses counting
 - If Up = 1, CNT is counting up from user selected value to 65535.
 - If Up = 0, CNT is counting down from user selected value to 1.

13 Pulse Width Modulator Macrocell (PWM)

The SLG47105 has two PWM blocks. Inputs/Outputs for the macrocells are configured from the connection matrix with specific logic functions being defined by the state of NVM bits.

PWM macrocell features:

- 8-bit (7-bit) PWM Resolution
- I²C/Matrix/Auto dynamically changeable Duty Cycle
- Changeable Period by changing PWM clock source
- Flexible OSC-integrated divider for PWM period selection
- I²C Duty cycle read/write
- Synchronous change of all PWM blocks by sequential I²C write command
- Configurable dead band option for OUT+ and OUT-
- 16 Preset Duty Cycle Registers Switching Mode (for PWM sine or other waveforms)
- Autostop at 0 % and 100 % of PWM duty cycle value
- Synchro OFF Mode (wait for PWM period end before stop block)
- Inv/non-Inv macrocell Output options
- From 0 %, 0.4 % to 99.6 %, 100 % Duty cycle for 8-bit resolution.

13.1 8-BIT/7-BIT PWM RESOLUTION

When configured as PWM, this macrocell has an 8-bit resolution. It is also possible to select 7-bit PWM resolution if the higher PWM frequency is needed.

The PWM block consists of two 8-bit counters. First one, named PWM Period CNT, is used to create PWM period and the second one, named PWM Duty Cycle CNT, is used to set PWM Duty Cycle and to make dynamic changes in PWM functionality.

There is an ability to change the Duty Cycle from 0 % to 100 %. The PWM duty cycle step is 0.4 % for 8-bit resolution and 0.8 % for 7-bit resolution mode. This step is constant in the whole range. Both 0 % and 100 % are included.

13.2 PWM INPUTS

- Duty Cycle CNT Up/Down is the signal for defining the direction of duty cycle change.
 - If Duty Cycle CNT Up/Down = 1, the duty cycle increases from current value up to 255.
 - If Duty Cycle CNT Up/Down = 0, the duty cycle decreases from current value down to 0.
- Duty Cycle CNT Keep/Stop.
 - When Keep function is selected (register [1461] = 0 for PWM0 and register [1479] = 0 for PWM1) HIGH logic level on this input disables the change of Duty Cycle CNT (clock for Duty Cycle CNT is blocked). However, PWM block still generates PWM output with a constant duty cycle.
 - When Stop function is selected (register [1461] = 1 for PWM0 and register [1479] = 1 for PWM1) HIGH logic level on this input disables the change of both Duty Cycle CNT and PWM Period CNT. Consequently, if Stop signal is active (logic HIGH) the output of PWM block remains constant.
Note that if no other macrocells except PWM block use the internal OSC, the logic HIGH on Stop input disables the work of internal OSC that is used as a clock source for PWM Period CNT. For this case, logic LOW on this input enables OSC again.
- Duty Cycle CNT CLK is the clock signal for incrementing/decrementing duty cycle value. Keep in mind that the actual duty cycle value will be updated during the next PWM period.
- Power-down (PD) is an active high-level signal for updating Duty Cycle to default user-defined value. Keep in mind, that user can change the default Duty Cycle value via I²C. The PD signal will apply right away when Sync Off (register [1301] = 1 for PWM0 and register [1475] = 1 for PWM1) and after PWM period is completed when Sync On (register [1301] = 0 for PWM0 and register [1475] = 0 for PWM1, (**Note**)). HIGH logic level on PD input disables the change of all PWM internal counters and stops the internal oscillator (if internal OSC isn't used by other macrocells) (see Section 13.10 Sync On/Off setting for Power-down signal). This function is individual for each PWM block.
Note that for async mode a minimal time duration for HIGH level at PD input is 100 ns, which guarantee PWM response. A pulse shorter than 100 ns might be ignored. An input pulse will be extended internally to this minimal required time to power down the PWM block.
- Ext PWM Period CNT CLK is clock input for PWM Period CNT. The clock at this input defines PWM signal frequency. PWM Period CNT CLK comes from the internal predefined clock or from the matrix for the high flexibility of PWM frequency.

Note: First PWM period will be 2-3 clocks longer after PD signal is released.

13.3 PWM OUTPUTS

- OUT+: PWM positive output
- OUT- : PWM negative output

- PWM_PERIOD: PWM start period pulse (the duration of the high level is equal to one period of the PERIOD CNT CLK)

13.4 I²C/MATRIX/AUTO DYNAMICALLY CHANGEABLE DUTY CYCLE AND PERIOD

Duty Cycle in PWM macrocell can be changed in two ways:

1. PWM Duty Cycle CNT block has two parameters: Counter Data and Current Counter Value. The Current Counter Value defines PWM Duty Cycle. Counter Data of PWM Duty Cycle CNT can be changed by I²C commands with a reload into Current Counter Value. In this case, I²C Master can change PWM Duty Cycle by I²C. Therefore, Counter Data of PWM Duty Cycle CNT must support change via I²C.

2. Matrix changeable Duty Cycle. In this case "Duty Cycle CNT CLK" and "Duty Cycle CNT Up/Down" inputs are used. Rising edge at "Duty Cycle CNT CLK" changes Current Counter Value corresponding to "Duty Cycle CNT Up/Down" input state: if "Duty Cycle CNT Up/Down" is LOW then Current Counter Value decreases and vice versa.

PWM period (frequency) can be changed only by changing PWM Period CNT Clock source. There are several different clock options available for user selection. Therefore, for PWM frequency flexibility an OSC-integrated CNT divider can be used.

13.5 I²C PWM DUTY CYCLE READ/WRITE

The master I²C should be able to reliably read and write duty cycle value into PWM block. Synchro Buffer is used for correct I²C reading of actual PWM duty cycle. The I²C command has some time duration. Synchro Buffer captures actual PWM duty cycle for read command and I²C Master can read this data without errors.

The I²C Master can change PWM duty cycle via I²C write command. The newly written PWM duty cycle value will be loaded (but not applied) to the PWM block as the default value. The load will happen when I²C "stop" command is issued. To apply a default value to PWM block user must set the "I²C Trigger" bit to 1 via I²C interface. Note, that this value will be applied after the current PWM period.

If the user wants to change both PWM blocks simultaneously, I²C sequential write command must be used.

Note: Avoid the change of PD signal during I²C read, since it causes the buffer value to update.

13.6 FLEXIBLE OSC-INTEGRATED DIVIDER

The OSC-integrated divider is built into 25 MHz OSC to configure the PWM period. This divider can be used for other chip resources. There is 8-bit Counter with the source from OSC pre-divider and output to the matrix or directly to CNT/DLY block as one possible selection. In many cases, for all PWM macrocells, the same clock frequency is used. It is possible to use this Flexible OSC divider for fine frequency tuning of PWM cells.

The counter in flexible divider can be enabled/disabled by the register bit [741] only. When the counter in flexible divider is enabled it will start to count down from the counter data till 0. That is why the frequency division is counter data + 1. Minimum frequency after Flexible OSC-integrated Divider is at least twice smaller than input Flexible OSC-integrated Divider frequency. Counter won't count with 0b00000000 counter data. There is a separate register bit selection to enable the flexible divider output to the connection matrix.

Counter flexible divider resets with POR or RESET signal.

13.7 INVERTED OUTPUT OPTION

By default, PWM output begins from HIGH logic level and after reaching duty cycle value, output changes to LOW logic level. Optionally the user can invert outputs of PWM block.

Each PWM macrocell Outputs has an inverter option enabled by registers. It is necessary for simple driving of different LED types (common Anode/common Cathode), and others. Each OUT+ and OUT- outputs has one separate register to select its inverted/non-inverted output option.

13.8 CHANGEABLE DEAD BAND OPTION FOR OUT+ AND OUT-

Dead band parameter is needed to drive external power FETs. The dead band helps to avoid short through for high power FETs. Dead band parameter is configurable for driving different external transistor. It is possible to select no dead band time or dead band equal to one, two or three PWM Period clock cycles.

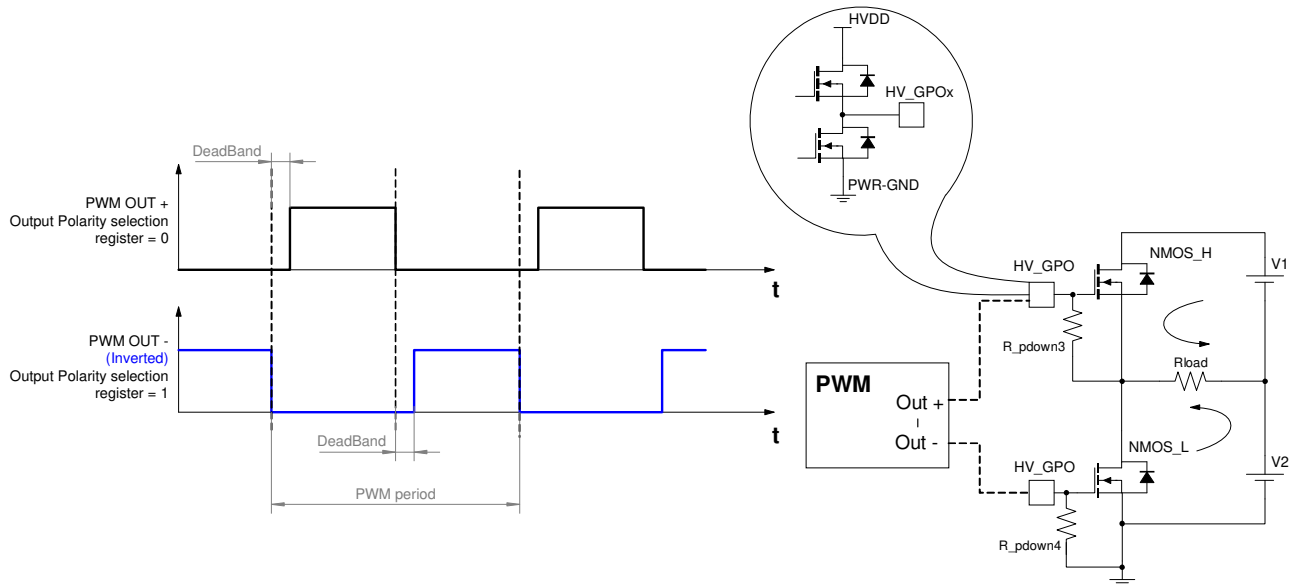

Figure 69: PWM Output Waveforms and Test Circuit Example for Driving NMOS FETs

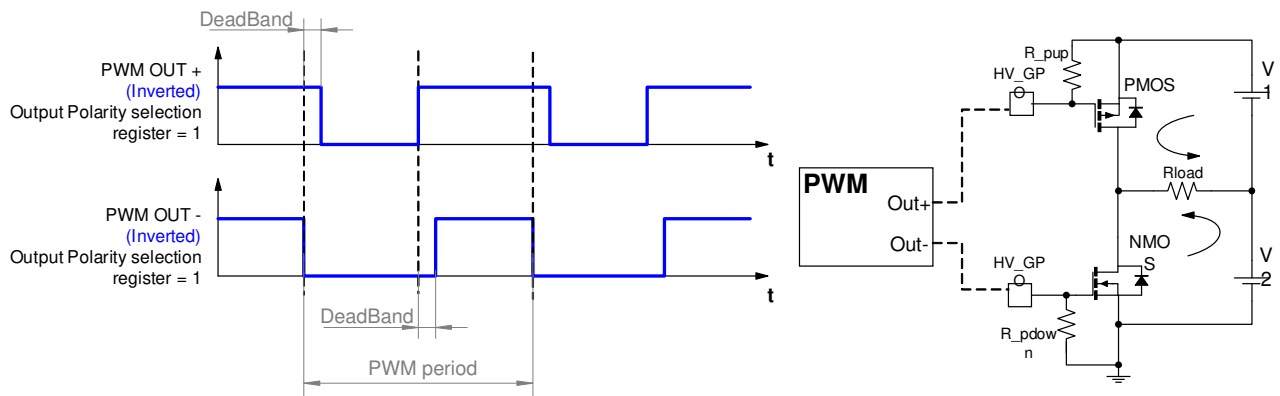

Figure 70: PWM Output Waveforms and Test Circuit Example for Driving NMOS and PMOS FETs

Note that external FETs must have Pull-up/Pull-down resistors between Gate and Source terminals to avoid unpredictable behavior of FETs when output pins of SLG47105 are in Hi-Z state (Sleep Mode).

The waveforms for Phase Correct PWM Mode are shown in Figure 71. Note that in Phase Correct PWM mode dead band delay is applied after phase correction, Figure 77.

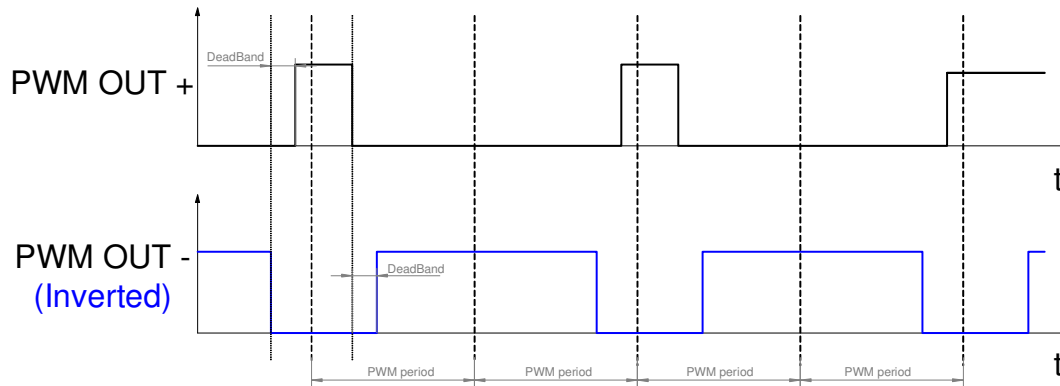

Figure 71: PWM Output Waveforms for Phase Correct PWM Mode

13.9 INITIAL PWM VALUE

Initial PWM duty cycle value is selected by Counter Data of PWM Duty Cycle CNT for regular mode. If Preset Registers Mode is selected, the initial value of PWM Duty Cycle CNT (Counter Data) is the preset registers address. Please refer to Section 13.11.

13.10 SYNC ON/OFF SETTING FOR POWER-DOWN SIGNAL

"SYNC On/Off" registers define the behavior of Power-down signal. This is the individual setting for each PWM macrocell. If this option is disabled (register [1301] for PWM0 = 1 and register [1475] = 1 for PWM0), the PWM output goes low right away by active Power-down, Figure 72. If this option is enabled (register [1301] for PWM0 = 0 and register [1475] = 0 for PWM0), the PWM block will finish the current PWM period and then will go low, Figure 75.

SYNC On/Off has no effect on duty cycle change via I²C. In the case of duty cycle change via I²C interface, new duty cycle value will be applied to PWM macrocell only after finishing the current PWM period.

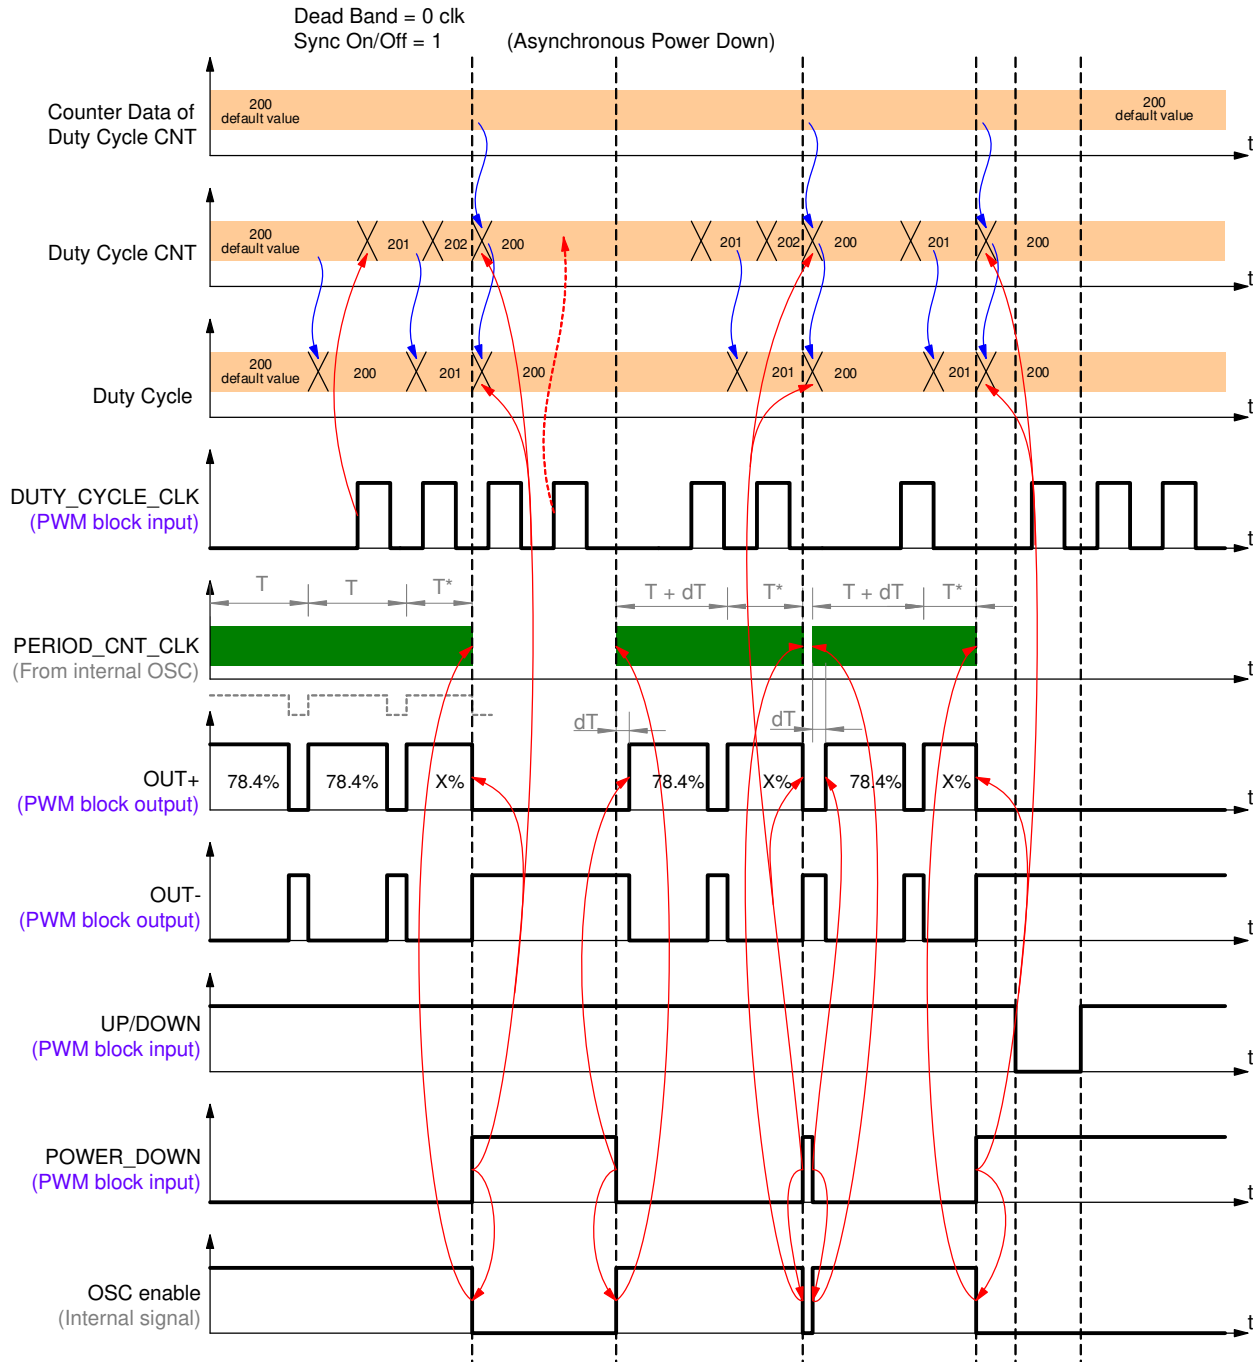

Figure 72: Power-Down with SYNC On/Off = 1 and Dead Band = 0 CLK

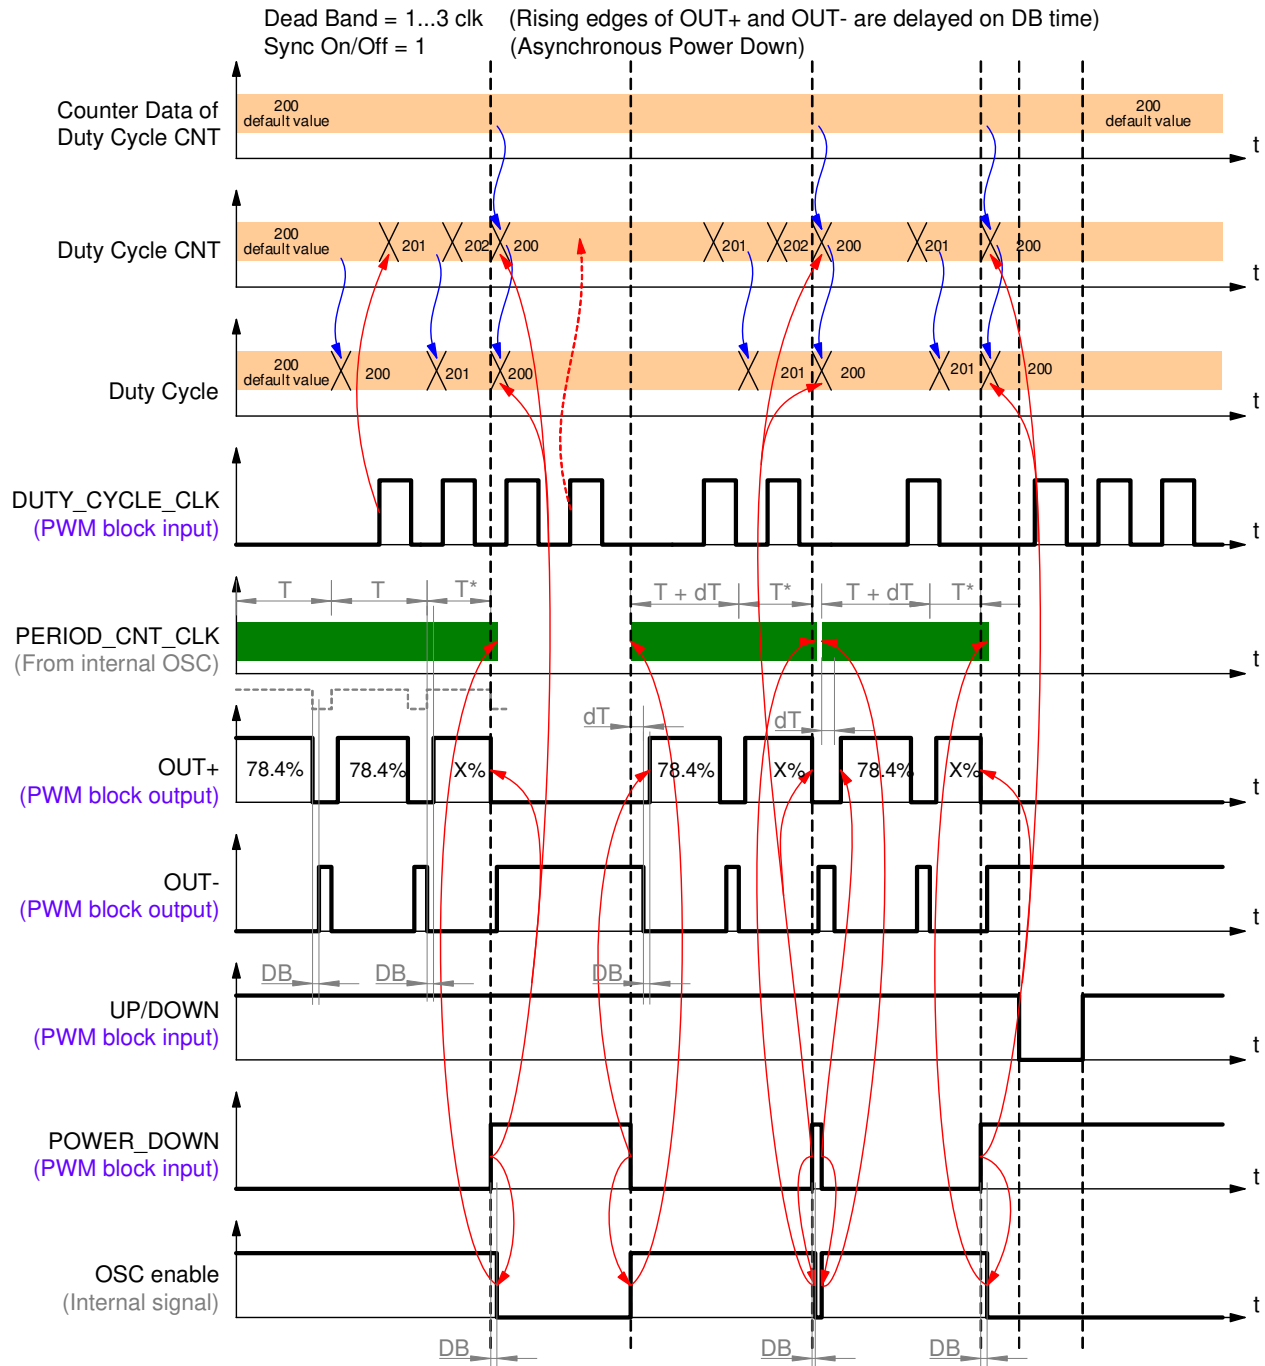

Figure 73: Power-Down with SYNC On/Off = 1 and Dead Band = 1 to 3 CLK

In Figure 72 to Figure 75:

- $dT = 2-3$ CLK and it is the additional number of clock pulses, that make first PWM period longer, after releasing PD signal;
- DB - user selected Dead Band time between OUT+ and OUT- ;
- T^* means the short period of x % duty cycle ($T^* < 255$ PERIOD_CNT_CLK), that is finished at the moment of PD signal coming.

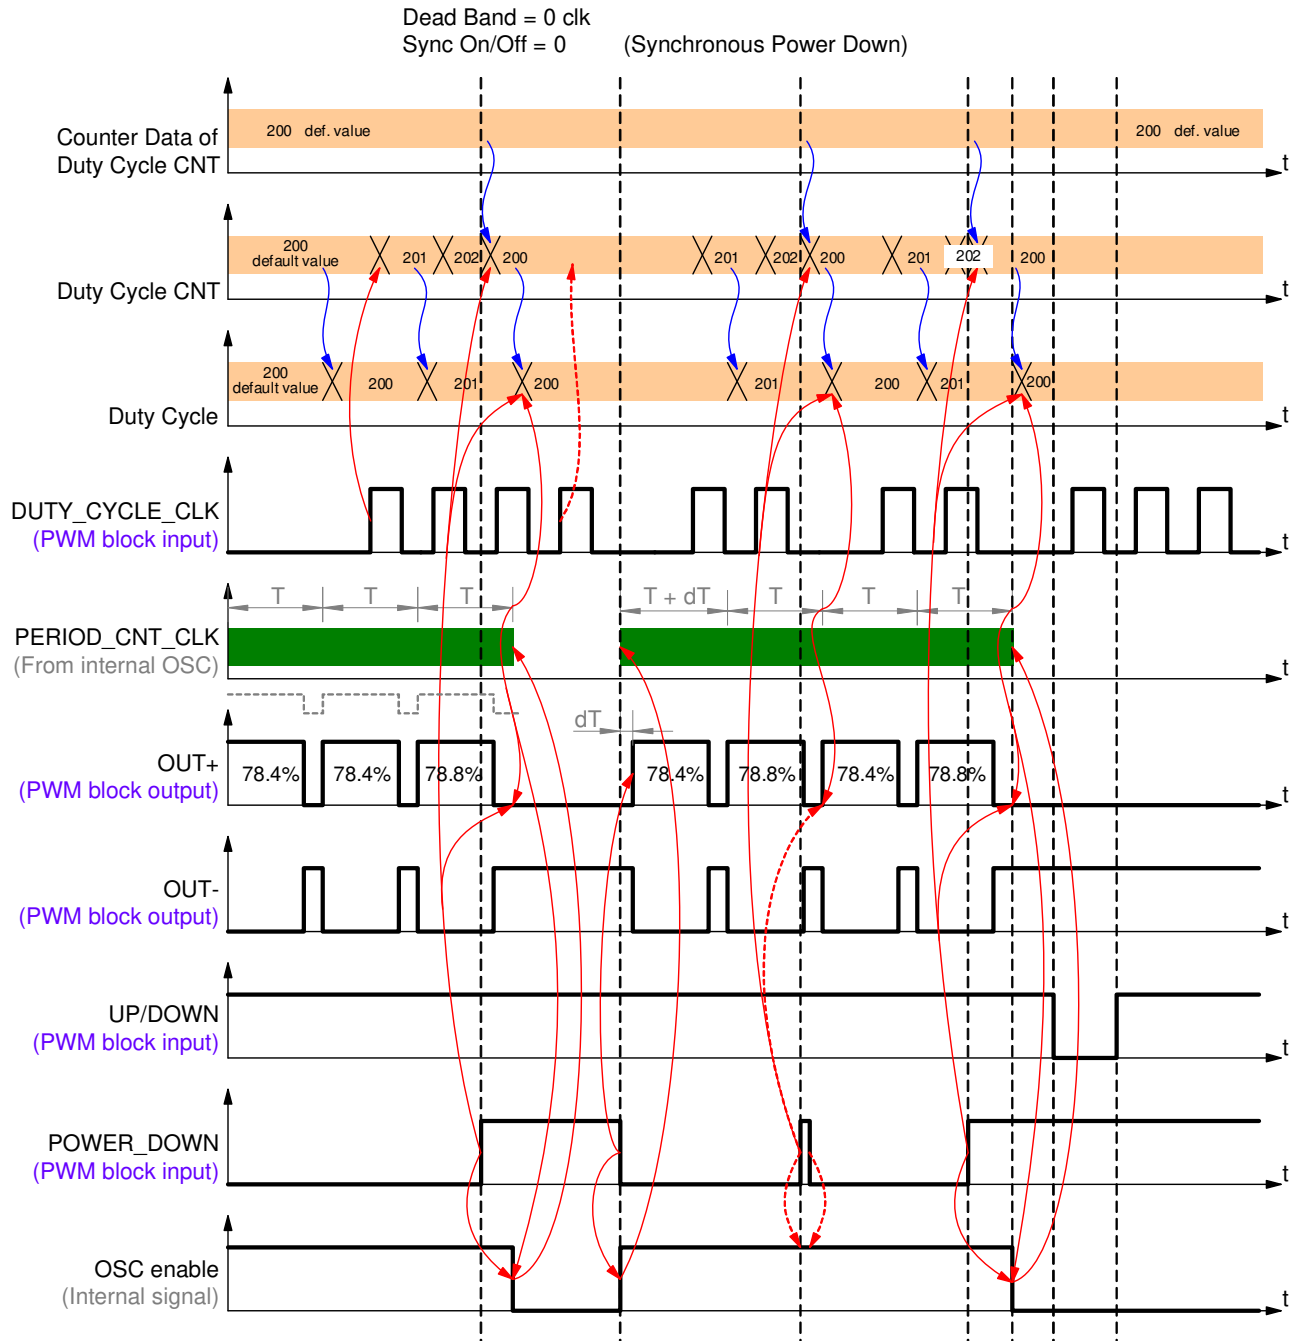

Figure 74: Power-Down with SYNC On/Off = 0 and Dead Band = 0 CLK

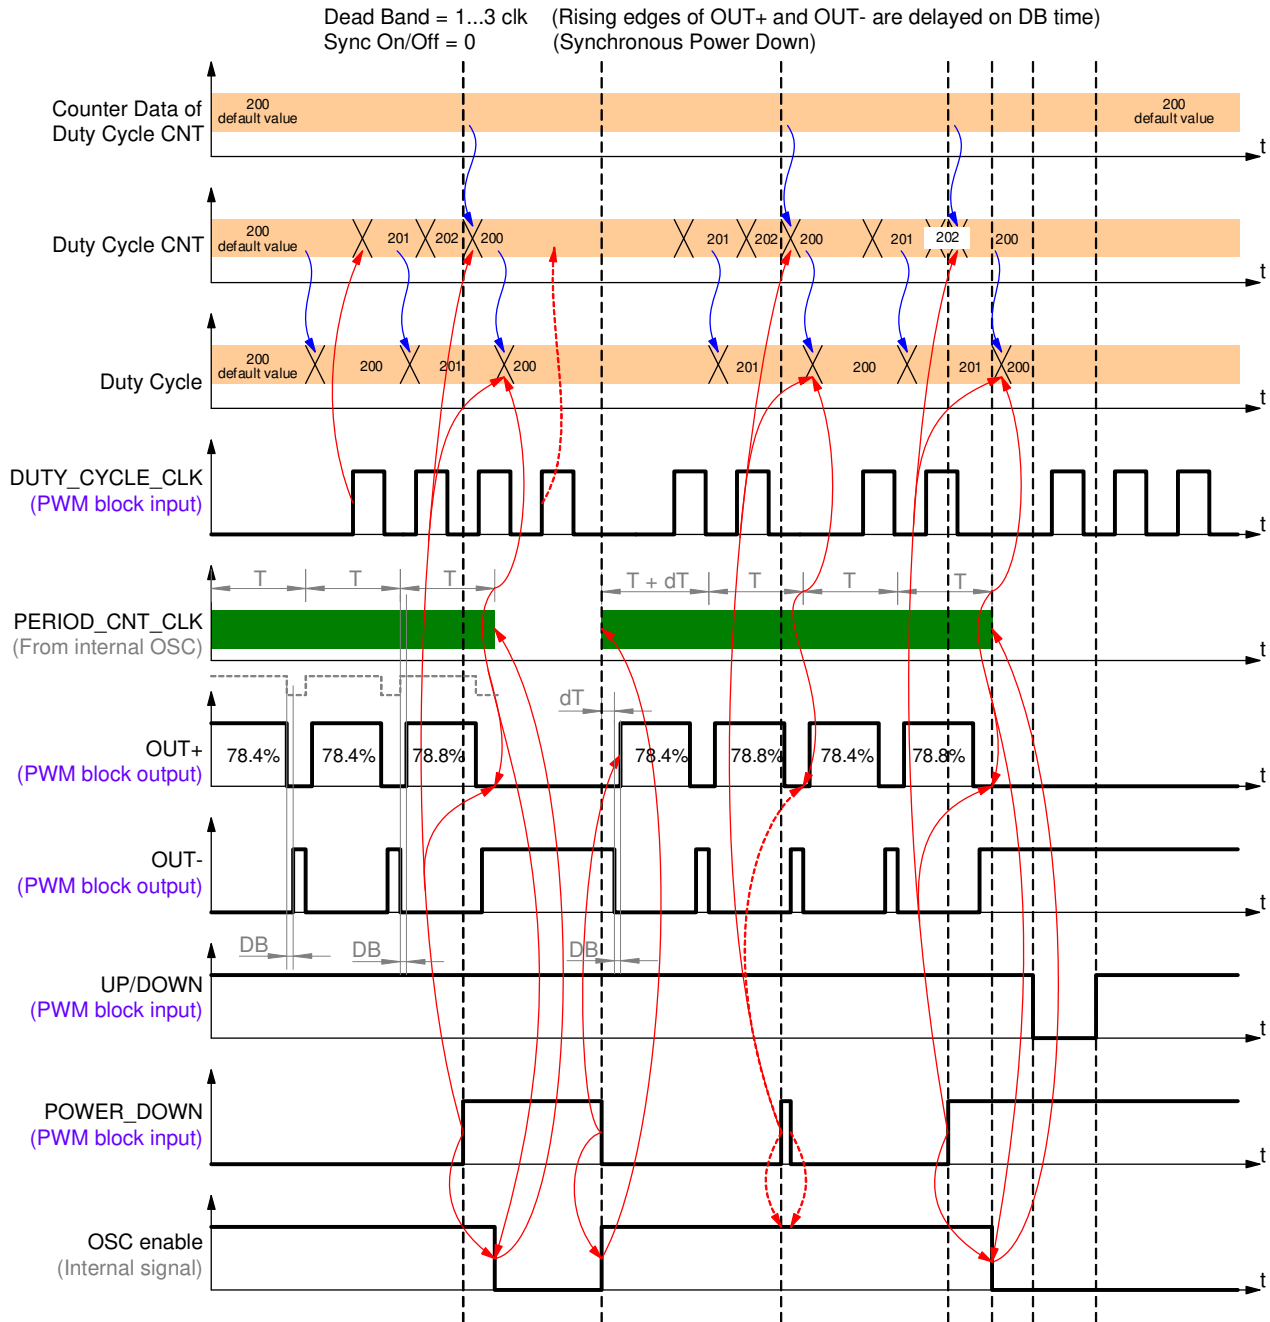

Figure 75: Power-Down with SYNC On/Off = 0 and Dead Band = 1 to 3 CLK

13.11 REGULAR/PRESET REGISTERS MODE

In Regular Mode the value of duty cycle is changed every rising edge on Duty Cycle CNT CLK input. In Preset Registers Mode the duty cycle is changed according to 16 predefined values, named Reg File, every rising edge on Duty Cycle CNT CLK input.

Selectable Preset registers are reserved to determine 16 different PWM Duty Cycle values. In Preset Registers mode the "Up/Down" input and "Duty Cycle CNT CLK input" change the address of Preset Register, that will be applied to PWM block at the rising edge on "Duty Cycle CNT CLK input".

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

One 16-byte Preset Register is shared between two PWM macrocells.

Each PWM block can select Reg File as Duty Cycle source. When the Reg File is selected as a source, there are three options: use all 16 bytes, use less significant 8 bytes, or use most significant 8 bytes. In this case, 4-bits (when using 16-Bytes Reg File) or 3-bits (when using any of 8 bytes Reg File) LSB Current Value of PWM Duty Cycle CNT is used to select data address inside the Reg File. The counter data of the Duty Cycle CNT will define the initial starting point in the Reg file. So, each PWM block has its own initial position in the Reg File.

Table 59: Regular/Preset Mode Registers

Register Name	Mode of Operation	Register Definition
PWMx: Duty Cycle source	Regular Mode	00: from PWM Duty Cycle CNT
		01: 8-byte MSB of RegFile
	Preset Registers Mode	10: 8-byte LSB of RegFile
		11: 16-byte RegFile

For more detailed description see [Table 61](#) and [Table 62](#).

13.12 PWM CONTINUOUS/AUTOSTOP MODE

“Continuous/Autostop mode” register enables Autostop mode. This mode can be used with both Preset Registers or Regular Mode.

If PWM block works in Continuous Mode (register [1302] = 0 for PWM0 or register [1476] = 0 for PWM1), PWM Duty Cycle CNT will overflow when it reaches boundaries. For example, for PWM Duty Cycle Counter counts up: 254th → 255th → 0th → 1st, and for PWM Duty Cycle Counter counts down: 1st → 0th → 255th → 254th ...

Or in Preset Registers Mode, when Continuous Mode is selected (register [1302] = 0 for PWM0 or register [1476] = 0 for PWM1): counting up 14th → 15th → 0th → 1st, and counting down 1st → 0th → 15th → 14th ...

If Autostop mode is active (register [1302] = 1 for PWM0 or register [1476] = 1 for PWM1), PWM duty cycle counter will stop when it reaches boundaries. The conditions of Autostop are the next:

- PWM Duty Cycle reaches the value 0 in Regular Mode or Least Significant Byte of Preset registers in Preset Registers Mode, and Up/Down is LOW logic level (counting Down).
- PWM Duty Cycle reaches the value 255 (127 in 7-bit submode) in Regular Mode or Most Significant Byte of Preset registers in Preset Registers Mode and Up/Down is HIGH logic level (counting Up).

13.13 INTERNAL OSCILLATOR AUTO DISABLE MODE

There is an OSC Auto Disable/Enable control, in which internal OSC is enabled only when it is required for PWM block. This Auto Disable Mode will operate only if user selects internal oscillator as a clock source for PWM Period Clock Counter ("PWM0 Period Clock Source selection" registers have a value from b0000 to b1001).

If the user selected PWM Period CNT overflow event as a clock source for Duty Cycle Counter (registers [1469:1468] = 01, or registers [1469:1468] = 10, or registers [1469:1468] = 11 for PWM0 and registers [1485:1484] = 01, or registers [1485:1484] = 10, or registers [1485:1484] = 11 for PWM1), then no clocks will be on Duty Cycle Counter Clock input when PWM enters to Autostop State (see [Table 60](#)).

The conditions, in which internal OSC will be automatically disabled, are shown in [Table 60](#).

Table 60: Conditions for Disabling/Enabling an Internal Oscillator

N0	Disable Condition	Delay before OSC in disabled	Enable Condition
1	PD signal goes HIGH	Disable OSC immediately if SYNC On/Off register [1301] = 1 for PWM0 and register [1475] = 1 for PWM1 Disable OSC after current duty cycle period if SYNC On/Off register [1301] = 0 for PWM0 and register [1475] = 0 for PWM1	PD signal goes LOW

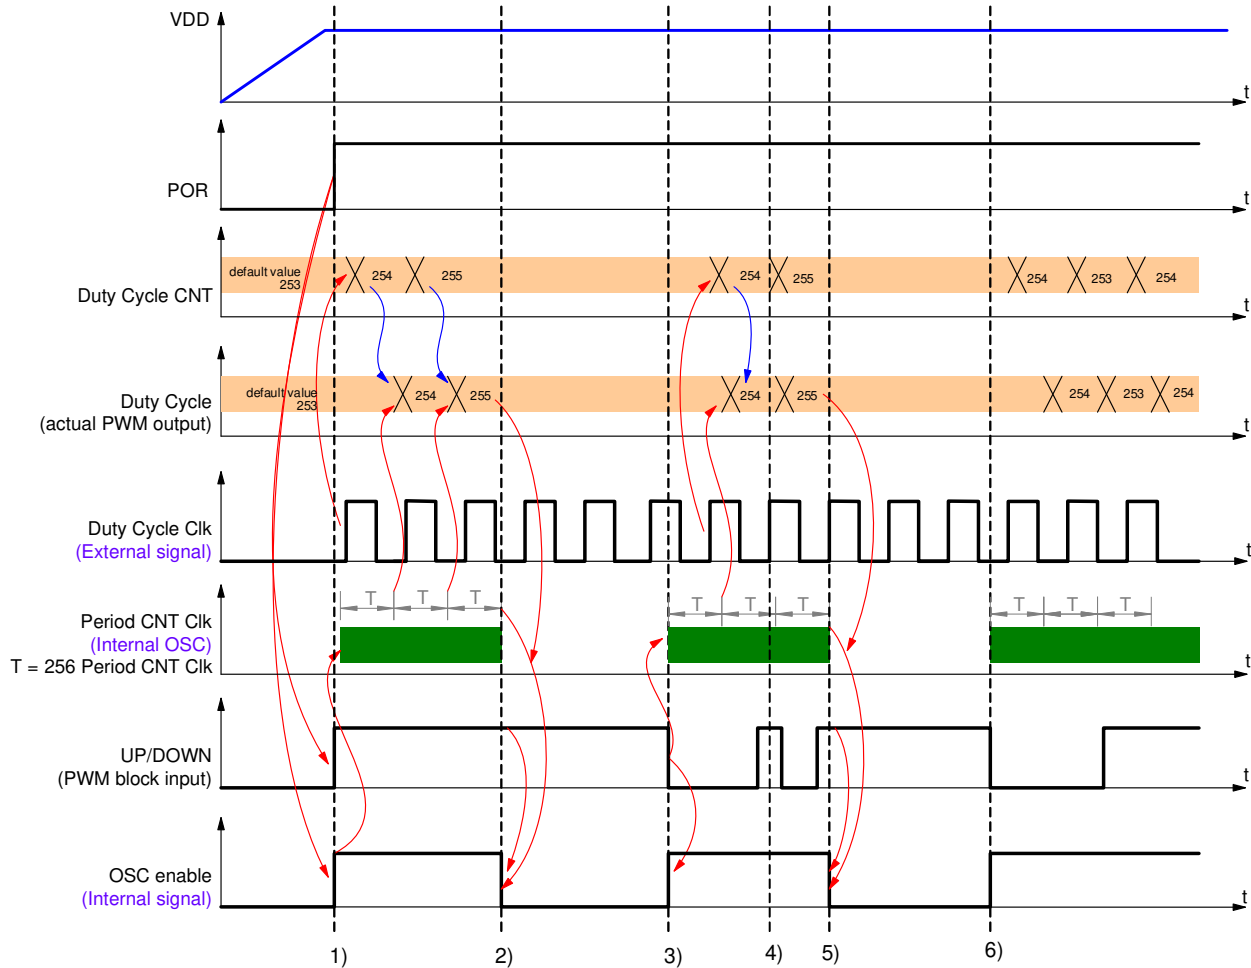

Table 60: Conditions for Disabling/Enabling an Internal Oscillator (Continued)

N0	Disable Condition	Delay before OSC in disabled	Enable Condition
2	Stop signal goes HIGH	Disable OSC immediately	Stop signal goes LOW
3	Up/Down is logic HIGH (counting up) and actual PWM value is 255 (127 for 7-bit submode), "PWM boundary OSC automatically disable" (register [1303]= 1 for PWM0 or register [1477] = 1 for PWM1) "Continuous/Autostop mode"(register [1302]= 1 for PWM0 or register [1476] = 1 for PWM1) Figure 76	Disable OSC after one full PWM period.	Up/Down signal changes its level to logic LOW (count down) Figure 76
4	Up/Down is logic LOW (counting down) and actual PWM value is 0, "PWM boundary OSC automatically disable"(register [1303]= 1 for PWM0 or register [1477] = 1 for PWM1) and "Continuous/Autostop mode"(register [1302]= 1 for PWM0 or register [1476] = 1 for PWM1)	Disable OSC after one full PWM period.	Up/Down signal changes its level to logic HIGH (count up)

Note 1 If PWM boundary OSC automatically disable register [1303] = 1 for PWM0 or register [1477] = 1 for PWM1 and PWM works with Preset Registers (registers [1467:1466] = 01 or registers [1467:1466] = 10, or registers [1467:1466] = 11 for PWM0 and registers [1483:1482] = 01 or registers [1483:1482] = 10, or registers [1483:1482] = 11 for PWM1), internal OSC will stop if Preset Registers Index = 15 (7 when LSByte mode of Preset Registers is used) the Preset Register Index remains unchanged until Up/Down signal changes. The same behavior has zero Preset Register Index (8 when MSByte mode of Preset Registers is used). When this index will be reached and OSC Auto Disable Mode is active the Preset Register Index remains unchanged until Up/Down signal changes.

Note 2 Other macrocells that use OSC, can start it or keep it enabled even if OSC Auto Disable Mode is active and condition for disabling OSC occurs.

Note 3 If dead band is different from 0, then OSC will be disabled for Dead Band Time later.

Figure 76: Example of PWM Auto Oscillator Control

In the example in [Figure 76](#), Duty Cycle CLK is external to PWM block signal, Period CNT CLK is a signal from internal OSC. "PWM boundary OSC automatically disable" register [1303] = 1 for PWM0 or register [1477] = 1 for PWM1. Autostop Mode is active too ("Continuous/Autostop mode" register [1302] = 1 for PWM0 or register [1476] = 1 for PWM1). The key events of Autostop are the next:

- Event 1) after chip start-up, OSC is enabled. The clock from internal OSC is used to generate PWM period. Duty Cycle CNT counts up since Up/Down input of PWM macrocell is logic HIGH. Note that first OSC pulse is delayed when OSC becomes enabled (see [Table 20](#)).
- Event 2) the value of Duty Cycle CNT is updated every rising edge at Duty Cycle CLK input. This value becomes valid at the beginning of every PWM period.
- When the Duty Cycle value of 100 % is reached and Up/Down input is logic HIGH, PWM macrocell disables internal OSC after one full PWM period.
- Event 3) internal OSC starts working because Up/Down signal becomes LOW and Duty Cycle = 100 %. This is the scenario for starting OSC after it was automatically disabled.
- Event 4) the Up/Down signal changes the direction of Duty Cycle counting because at the moment of signals rising edge on Duty Cycle CLK input, the level of Up/Down input is logic HIGH.
- Event 5) OSC is disabled because the value of Duty Cycle is 100 % and at the beginning of the next PWM period the Up/Down input is logic HIGH.
- Event 6) Since Up/Down goes low and Duty Cycle is equal to 100 %, this is the scenario for starting up the OSC.

13.14 PHASE CORRECT PWM MODE

In normal mode, PWM output is HIGH, then LOW for each PWM period. When Phase correct PWM (also called Center Align) register is active (register [1460] = 1 for PWM0 or register [1478] = 1 for PWM1), the PWM output is HIGH, then LOW for the first period, then LOW again and HIGH for the second period. So, there are less edges (or less output switches) for the Phase correct PWM mode.

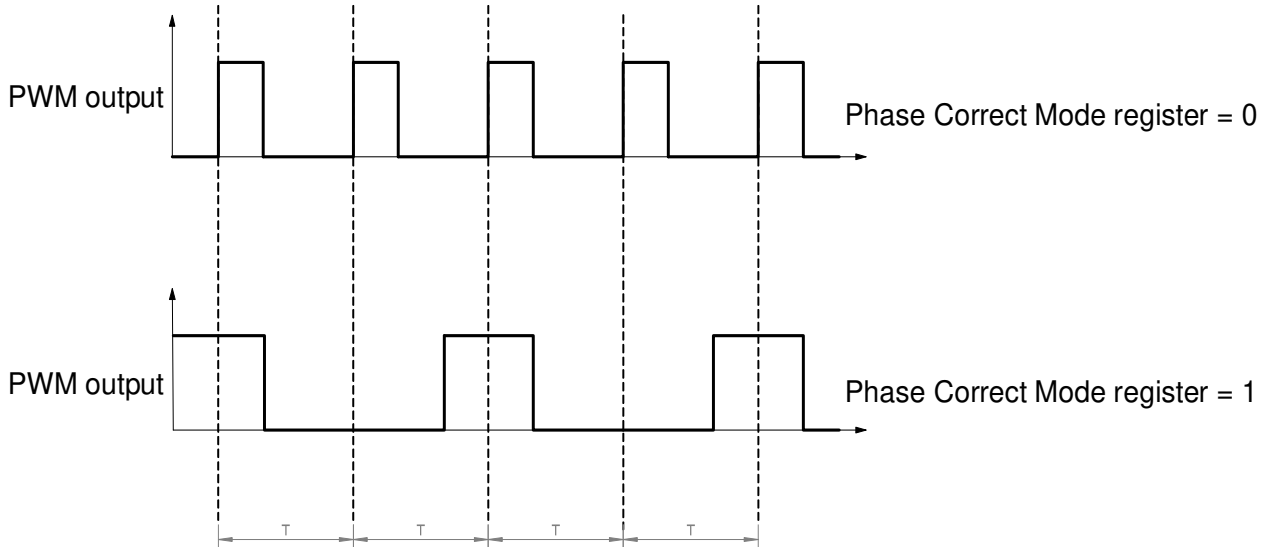

Figure 77: Phase Correct PWM Mode

13.15 PWM PERIOD OUTPUT

PWM_PERIOD output indicates the start of the new PWM period at PWM_OUT+. This output doesn't depend on the PWM duty cycle. The duration of the high level is equal to one period of the PERIOD_CNT_CLK.

"Keep/Stop" register defines which function will be performed by "Duty Cycle CNT Keep/Stop" input. Keep/Stop signal is active HIGH level.

"PWM Period Clock Source selection" registers define clock source for "PWM Period CNT CLK" input: from the matrix, from OSCx and OSCx dividers, from the flexible OSC-integrated divider. Also, there is an option to select counter overflow condition as a source for PWM Period Clock.

"PWM: Duty Cycle Source selection" defines the clock source for changing the duty cycle. It can be:

- clock source from the connection matrix;
- clock pulse that is generated after the end of PWM cycle period (PWM Period Counter overflow). This pulse is generated every 255 (for 8-bit option) or 127 (for 7-bit option) PWM Period Clocks;
- clock pulse that is generated once per 2 PWM period, or every 510 (for 8-bit option) or 254 (for 7-bit option) PWM Period Clocks;
- clock pulse that is generated once per 8 PWM period, or every 2040 (for 8-bit option) or 1016 (for 7-bit option) PWM Period Clocks.

"I²C Trigger" register allows to update duty cycle value via I²C command:

- When I²C_Trigger = 0, PWM duty cycle isn't updated;
- When I²C_Trigger = 1, PWM duty cycle is updated from register at I²C stop pulse after the current PWM period is completed. The I²C_Trigger bit will be automatically cleared after the I²C stop pulse.

"SYNC On/Off" registers define the Power-down signal behavior on PWM block. This is the individual setting for each PWM macrocell. If this option is disabled (register [1301] = 1 for PWM0 or register [1475] = 1 for PWM1), then PWM output is changed right away by active Power-down. If this option is enabled (register [1301] = 0 for PWM0 or register [1475] = 0 for PWM1), the

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

PWM block will finish the current PWM period and then will react to Power-down signal.

"Continuous/Autostop mode" register enables Autostop mode. This mode can be used with both Preset Registers or Regular Mode. If PWM block works in Continuous Mode (register [1302] = 0 for PWM0 or register [1476] = 0 for PWM1), PWM Duty Cycle CNT will overflow when it reaches boundaries. For example, for PWM Duty Cycle Counter counts up: 254th → 255th → 0th → 1st, and for PWM Duty Cycle Counter counts down: 1st → 0th → 255th → 254th ... If Autostop mode is active (register [1302] = 1 for PWM0 or register [1476] = 1 for PWM1), PWM duty cycle counter will stop when it reaches boundaries. Please refer to Section 13.12.

"PWMx boundary OSC disable" is the function, that allows disabling internal oscillator when there is no need for PWM to be clocked (boundary is reached in Autostop Mode only). This feature is useful for energy saving, but the user can optionally disable it and keeps the oscillator always enabled.

"Phase Correct mode". In normal mode, PWM output is HIGH, then LOW for each PWM period. When Phase correct PWM (also called Center Align) register is active (register [1460] = 1 for PWM0 or register [1478] = 1 for PWM1), then PWM output is HIGH, then LOW for the first period, then LOW again, and HIGH for the second period. So, there are less edges (or less output switches) for the Phase correct PWM mode.

"Duty Cycle source" (registers [1467:1466] for PWM0 or registers [1483:1482] for PWM1) defines the Regular Mode of operation (registers [1467:1466] = 00 for PWM0 or registers [1483:1482] = 00 for PWM1) or Preset Registers Mode (registers [1467:1466] = 01, registers [1467:1466] = 10, registers [1467:1466] = 11 for PWM0 or registers [1483:1482] = 01, registers [1483:1482] = 10, registers [1483:1482] = 11 for PWM1). In Regular Mode, the value of duty cycle is changed every rising edge on Duty Cycle CNT CLK input. In Preset Registers Mode the duty cycle is changed according to values, saved in 8-byte MSB of RegFile (registers [1467:1466] = 01 for PWM0 or registers [1483:1482] = 01 for PWM1), 8-byte LSB of RegFile (registers [1467:1466] = 10 for PWM0 or registers [1483:1482] = 10 for PWM1) or 16-byte of RegFile (registers [1467:1466] = 11 for PWM0 or registers [1483:1482] = 11 for PWM1). The address of RegFile value, that is applied to PWM block, is changed every rising edge on Duty Cycle CNT CLK input.

"OUT+ polarity selection" registers enable/disable inverted option for Output+ of PWM macrocell.

"OUT- polarity selection" registers enable/disable inverted option for Output- of PWM macrocell.

"Deadband selection" registers [1465:1464] for PWM0 and registers [1481:1480] for PWM1 chose dead band time between OUT+ and OUT- signals. It is 0, 1, 2, or 3 clock period of PWM Period CNT CLK signal.

"8-bit/7-bit PWM resolution". It is possible to select 7-bit instead of default 8-bit resolution for the PWM to increase the PWM speed. If the 7-bit resolution is selected, the maximum value of the duty cycle counter is 127.

14 Analog Comparators

There are two Rail-to-Rail General Purpose Analog Comparators (ACMP) macrocells in the SLG47105. In order for the ACMP cells to be used in a GreenPAK design, the power-up signals (ACMP0H_nPD, ACMP1H_nPD) need to be active. By connecting to signals coming from the Connection Matrix, it is possible to have each ACMP be on continuously, off continuously, or switched on periodically, based on a digital signal coming from the Connection Matrix. When ACMP is powered down, the output is low.

The General-Purpose Rail-to-Rail Analog Comparators are optimized for high-speed operation (ACMP0H and ACMP1H).

Each of the ACMP cells has a positive input signal that can be provided by a variety of external sources and can also have a selectable gain stage before connection to the analog comparator. Each of the ACMP cells has a negative input signal that is either created from an internal Vref or provided by a way of the external sources.

PWR UP = 1 => ACMP is powered up.

PWR UP = 0 => ACMP is powered down.

During power-up, the ACMP output will remain LOW, and then become valid 45 μ s (max) after power-up signal goes high for ACMP0H and ACMP1H. Input bias current < 1 nA (typ). The Gain divider is unbuffered and consists of 2 M Ω resistors. IN- voltage range: 0 - 2.016 V.

Each cell also has a hysteresis selection, to offer hysteresis of (0, 32, 64, 192) mV. The hysteresis option is available when using an internal Vref only.

ACMP0H IN+ options are GPIO5, V_{DD}

ACMP1H IN+ options are GPIO6, ACMP0H IN+ MUX output, Temp Sensor OUT

Figure 85: ACMPxH Power-On Delay vs. V_{DD}

15 Programmable Delay/Edge Detector

The SLG47105 has a programmable time delay logic cell that can generate a delay that is selectable from one of four timings (time2) configured in the GreenPAK Designer. The programmable time delay cell can generate one of four different delay patterns, rising edge detection, falling edge detection, both edge detection, and both edge delay. These four patterns can be further modified with the addition of delayed edge detection, which adds an extra unit of delay, as well as glitch rejection during the delay period. See Figure 86 for further information.

Note The input signal must be longer than the delay, otherwise it will be filtered out.

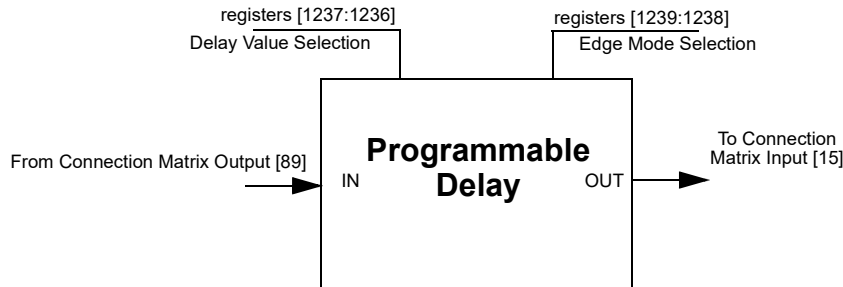

Figure 86: Programmable Delay

15.1 PROGRAMMABLE DELAY TIMING DIAGRAM - EDGE DETECTOR OUTPUT

Figure 87: Edge Detector Output

Please refer to [Table 13](#).

16 Additional Logic Function. Deglitch Filter

The SLG47105 has one Deglitch Filter macrocell with inverter function that is connected directly to the Connection Matrix inputs and outputs. In addition, this macrocell can be configured as an Edge Detector, with the following settings:

- Rising Edge Detector
- Falling Edge Detector
- Both Edge Detector
- Both Edge Delay

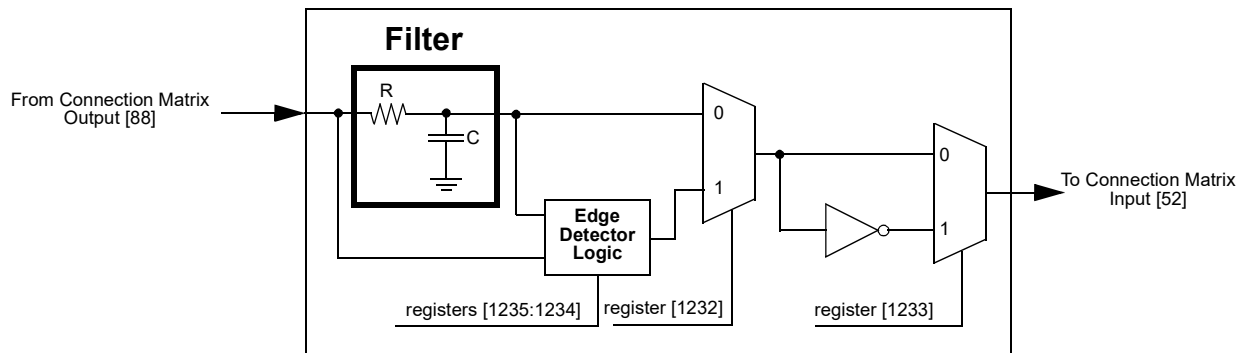

Figure 88: Deglitch Filter/Edge Detector

17 Voltage Reference

17.1 VOLTAGE REFERENCE OVERVIEW

The SLG47105 has a Voltage Reference (Vref) macrocell to provide references to the four analog comparators. This macrocell can supply a user selection of fixed voltage references, or temperature sensor output. The macrocell also has the option to output reference voltages on GPIO0. See [Table 63](#) for the available selections for each analog comparator.

Also, see [Figure 63](#), which shows the reference output structure.

17.2 VREF SELECTION TABLE

Table 63: Vref Selection Table

SEL	SEL[5:0]	Vref	SEL	SEL[5:0]	Vref
0	000000	0.032	32	100000	1.056
1	000001	0.064	33	100001	1.088

17.3 MODE SELECTION

Table 64: Mode Selection Table

Conditions	M[2]	M[1]	M[0]	Mode
GPIO0 isn't configured as Analog IO (registers [756:755] ≠ 11) OR GPIO0 OE is HIGH	0	0	0	Analog Power-down
	0	0	1	Analog Power-down
	0	1	0	Vref_OUT to ACMP only
	0	1	1	Vref_OUT to ACMP only
	1	0	0	Analog Power-down
	1	0	1	Vts_OUT to ACMP only
	1	1	0	Vts_OUT to ACMP only
	1	1	1	Analog Power-down
GPIO0 is configured as Analog IO (registers [756:755] = 11) AND GPIO0 OE is LOW	0	0	0	Analog Power-down
	0	0	1	Vref_OUT to GPIO0 only
	0	1	0	Vref_OUT to ACMP only
	0	1	1	Vref_OUT to GPIO0 and ACMP
	1	0	0	Vts_OUT to GPIO0 only
	1	0	1	Vts_OUT to ACMP only
	1	1	0	Vts_OUT to GPIO0 and ACMP
	1	1	1	Vref_OUT to GPIO0 bypass analog buffer

Note: Voltage Reference can be outputted to GPIO0 according to M[2:0] state when this GPIO is configured as Analog IO (registers [756:755] = 11) AND GPIO0 OE is LOW.

17.4 VREF BLOCK DIAGRAM

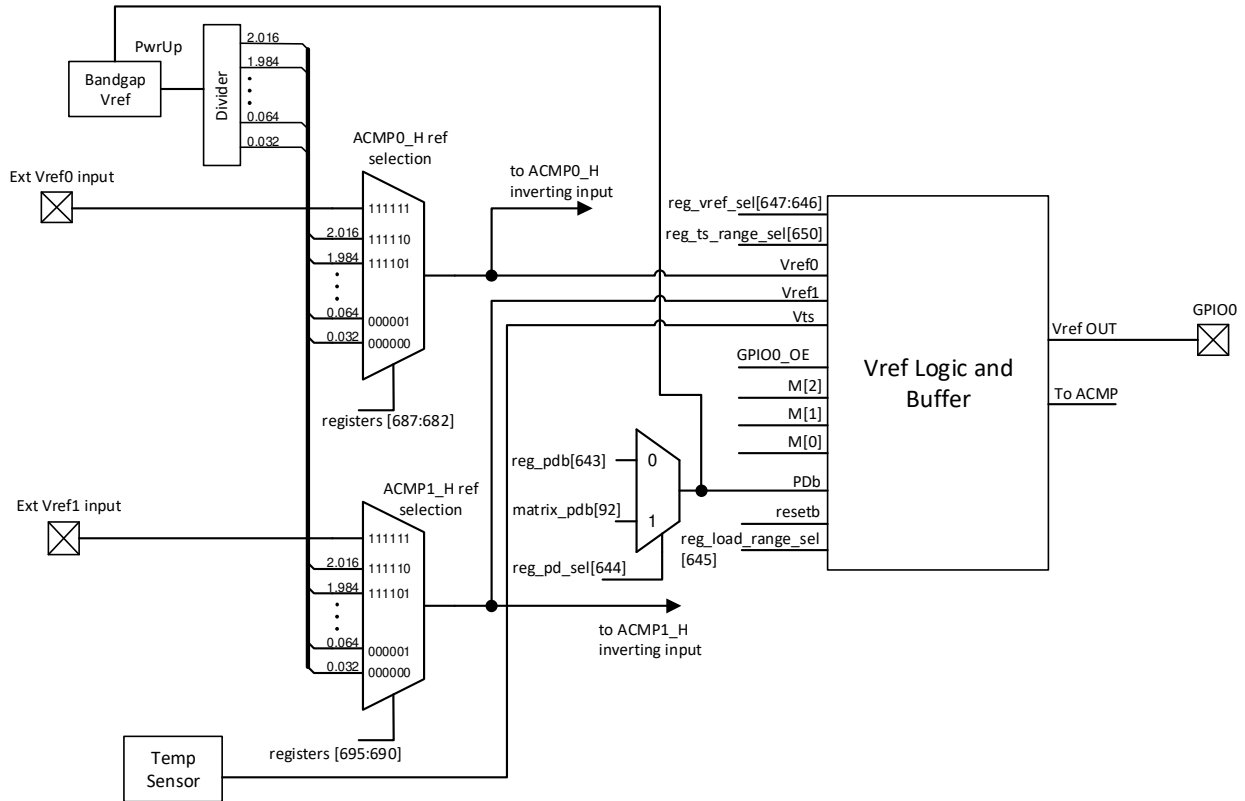

Figure 89: Voltage Reference Block Diagram

Note 1: reg_ts_range_sel register, that defines voltage range of Vref Block Output, is valid for Temp Sensor source only.

Note 2: reg_load_range_sel register should be set to 1 for better stability when the load resistance at GPIO0 is more than 100 kOhm. This option affects consumption current.

17.5 VREF LOAD REGULATION

Note 1 It is not recommended to use Vref connected to external pin without buffer.

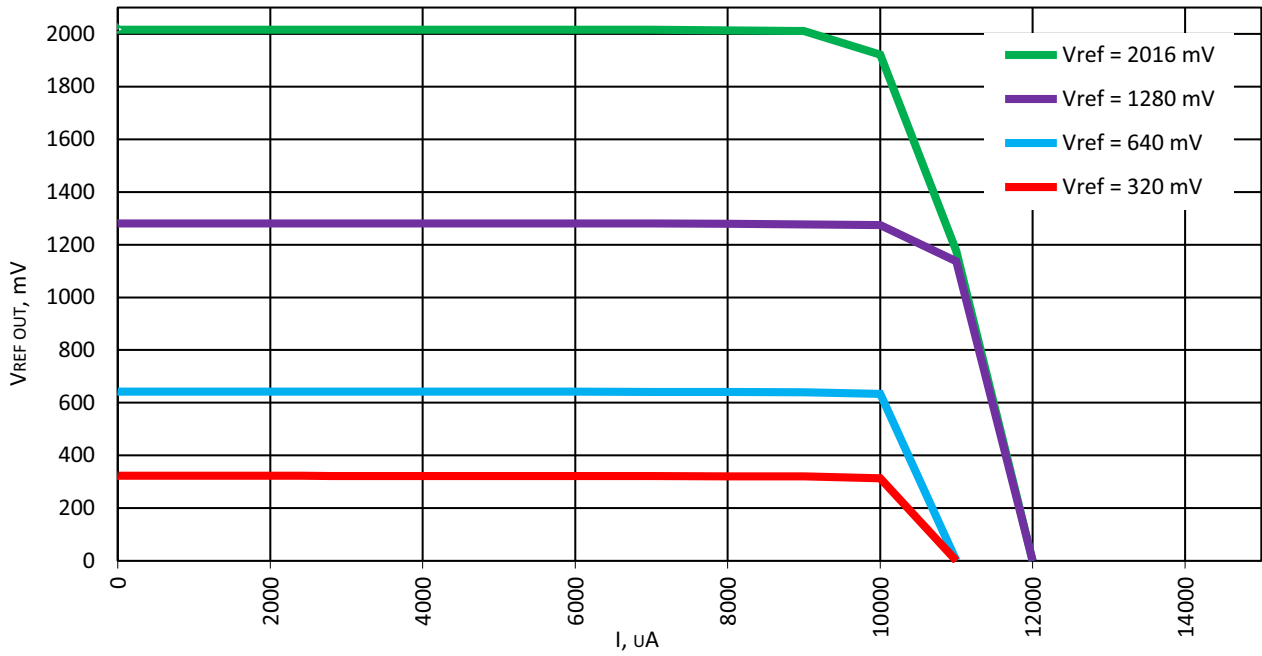

Figure 90: Typical Load Regulation, T = -40 °C to +85 °C, V_{DD} = 3.3 V, Buffer - Enabled

18 Clocking

18.1 OSC GENERAL DESCRIPTION

The SLG47105 has two internal oscillators to support a variety of applications:

- Oscillator0 (2.048 kHz)
- Oscillator1 (25 MHz).

There are two divider stages for each oscillator that gives the user flexibility for introducing clock signals to the connection matrix, as well as various other macrocells. The Pre-divider (first stage) for Oscillator allows the selection of /1, /2, /4 or /8, and /12 in Oscillator1(25 MHz) to divide down frequency from the fundamental. The second stage divider has an input of frequency from the Pre-divider, and outputs one of eight different frequencies divided by /1, /2, /3, /4, /8, /12, /24, or /64 on Connection Matrix Input lines [53], [54], [55], and [56]. Please see [Figure 91](#) for more details on the SLG47105 clock scheme.

Oscillator1 (25 MHz) has an additional function of 100 ns delayed startup, which can be enabled/disabled by register [722]. This function is recommended to use when analog blocks are used along with the Oscillator.

The Matrix Power-down/Force On function allows switching off or force on the oscillator using an external pin. The Matrix Power-down/Force-On (Connection Matrix Output [90], [91]) signal has the highest priority. The OSC operates according to the following table:

Table 65: Oscillator Operation Mode Configuration Settings

POR	External Clock Selection	Signal From Connection Matrix	Register: Power-Down or Force On by Matrix Input	Register: Auto Power-On or Force On	OSC Enable Signal from CNT/DLY Macrocells	OSC Operation Mode
0	X	X	X	X	X	OFF
1	1	X	X	X	X	Internal OSC is OFF, logic is ON
1	0	1	0	X	X	OFF
1	0	1	1	X	X	ON
1	0	0	X	1	X	ON
1	0	0	X	0	CNT/DLY requires OSC	ON
1	0	0	X	0	CNT/DLY does not require OSC	OFF

Note The OSC will run only when any macrocell that uses OSC is powered on.

18.2 OSCILLATOR0 (2.048 KHZ)

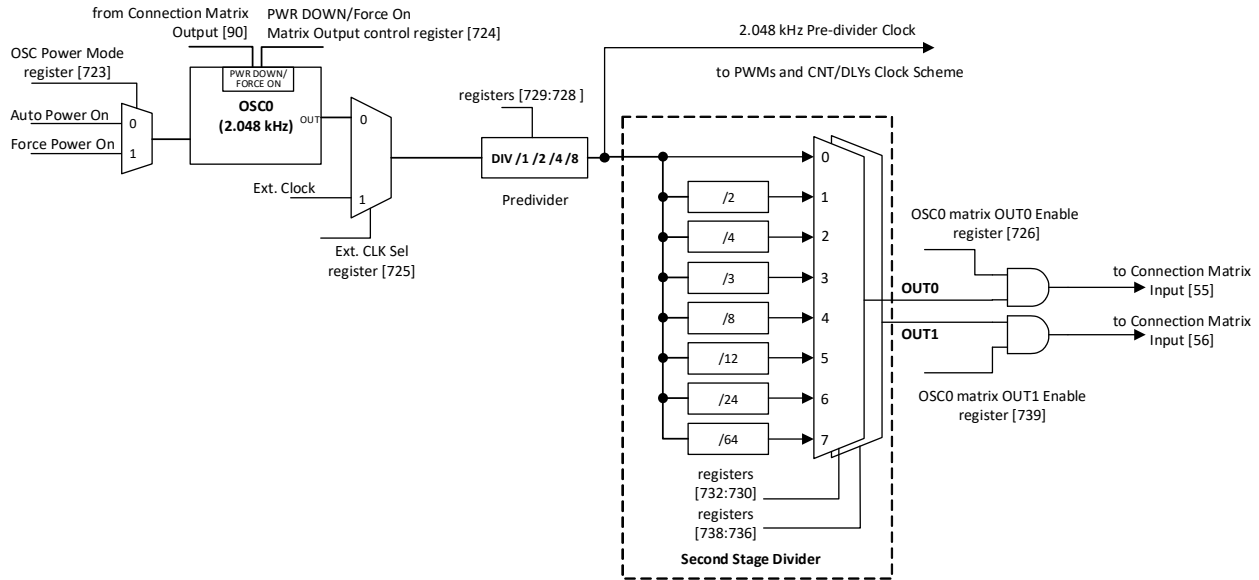

Figure 91: Oscillator0 Block Diagram

18.3 OSCILLATOR1 (25 MHZ)

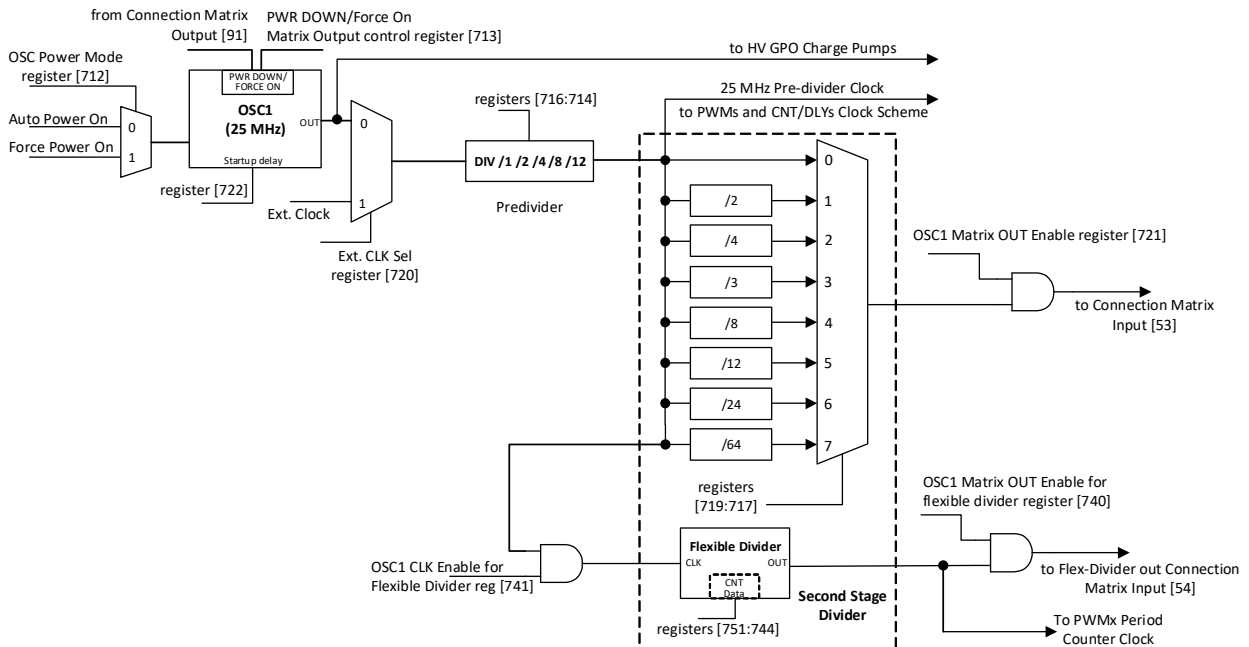

Figure 92: Oscillator1 Block Diagram

The OSC-integrated divider is built into 25 MHz OSC for saving chip resources. Actually, this divider is created especially for PWM, but it can be used for other chip resources thanks to its output to the matrix. There is 8-bit Counter with the source from

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

OSC pre-divider and output to the matrix. In many cases for all PWM macrocells, the same frequency is a need. In these cases, it is possible to use this PWM divider for fine frequency tuning of PWM cells by I²C or from NVM.

18.4 CNT/DLY CLOCK SCHEME

Each CNT/DLY within Multi-Function macrocell has its own additional clock divider connected to oscillators pre-divider. Available dividers are:

- OSC0/1, OSC0/8, OSC0/64, OSC0/512, OSC0/4096, OSC0/32768, OSC0/262144
- OSC1/1, OSC1/4

It is possible also to connect input from CNT(x-1) overflow or from Connection Matrix OUT.

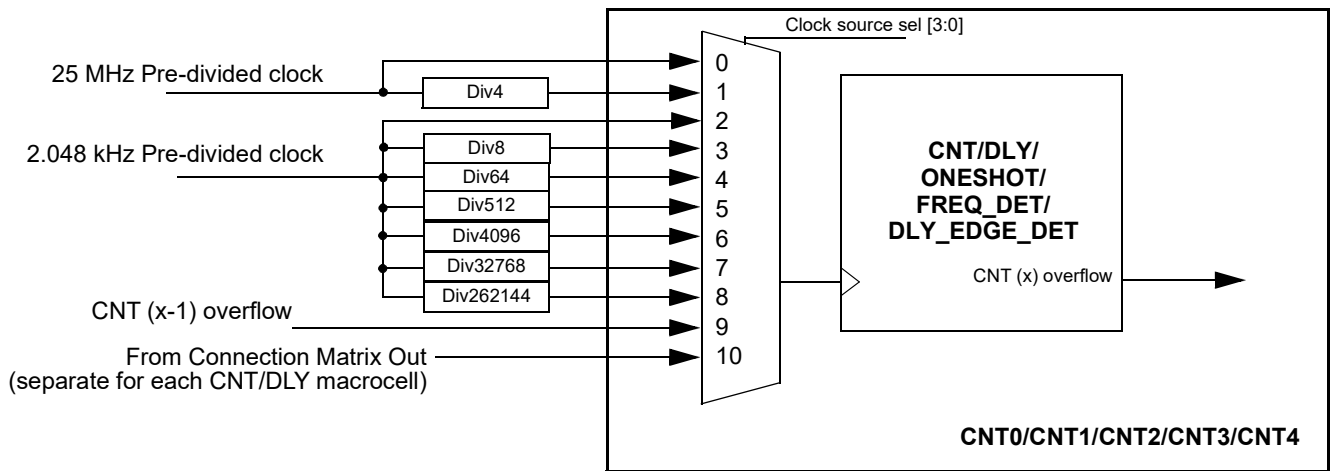

Figure 93: Clock Scheme

18.5 PWM CLOCK SCHEME

Each PWM macrocell has its own additional clock divider connected to oscillators pre-divider. Available dividers are:

- OSC1/1, OSC1/8, OSC1/64, OSC1/512, OSC1/4096, OSC1/32768, OSC1/262144
- OSC0/1, OSC0/4

It is possible also to connect input from Flexible Divider (OSC1 clock divider) or from Connection Matrix OUT.

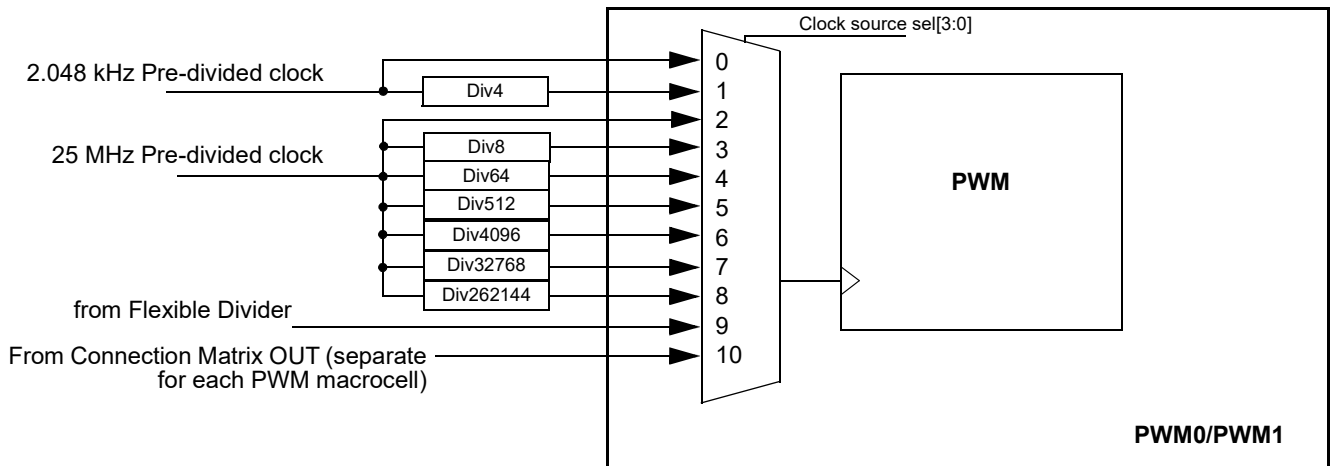

Figure 94: PWM Clock Scheme

18.6 EXTERNAL CLOCKING

The SLG47105 supports several ways to use an external, higher accuracy clock as a reference source for internal operations. Note that the Low Voltage Digital Input PIN type can only support up to 1 MHz.

18.6.1 GPIO1 Source for Oscillator0 (2.048 kHz)

When register [725] is set to 1, an external clocking signal on GPIO1 will be routed in place of the internal oscillator derived 2.048 kHz clock source. See [Figure 91](#). The low and high limits for external frequency that can be selected are 0 MHz and 10 MHz.

18.6.2 GPIO4 Source for Oscillator 1 (25 MHz)

When register [720] is set to 1, an external clocking signal on GPIO4 will be routed in place of the internal oscillator derived 25 MHz clock source. See [Figure 92](#). The external frequency range is 0 MHz to 20 MHz at $V_{DD} = 2.3$ V, 30 MHz at $V_{DD} = 3.3$ V, 50 MHz at $V_{DD} = 5.0$ V.

18.7 OSCILLATORS POWER-ON DELAY

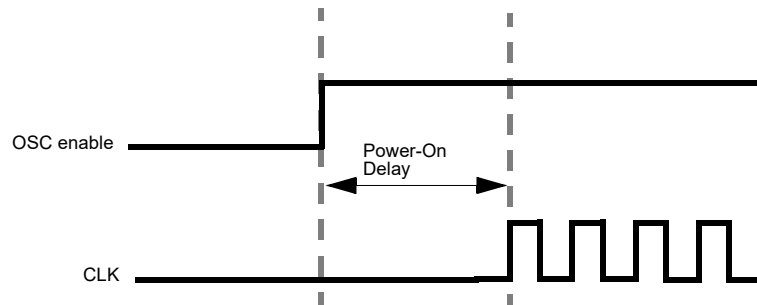

Figure 95: Oscillator Startup Diagram

Note 1 OSC power mode: “Auto Power-On”.

Note 2 “OSC enable” signal appears when any macrocell that uses OSC is powered on

19 Low Power Bandgap (LP_BG)

Low Power Bandgap is the analog part, that is used by analog macrocells in HV PAK, such as 25 M OSC1, ACMPs, HV GPOs, UVLO, and others. The high efficiency low power Bandgap consumes just 510 nA. However, it requires about 2 ms Start Up Time for stable functionality. For these reasons, it is recommended to keep LP_BG always on.

It is still possible to turn off the LP_BG through the connection matrix when no analog blocks are used.

Please note that OSC0 (2.048 kHz) does not use LP_BG.

20 Power-On Reset

The SLG47105 has a Power-On Reset (POR) macrocell to ensure correct device initialization and operation of all macrocells in the device. The purpose of the POR circuit is to have consistent behavior and predictable results when the V_{DD} power is first ramping to the device, and also while the V_{DD} is falling during Power-down. To accomplish this goal, the POR drives a defined sequence of internal events that trigger changes to the states of different macrocells inside the device, and finally to the state of the IOs.

20.1 GENERAL OPERATION

The SLG47105 is guaranteed to be powered down and non-operational when the V_{DD} voltage (voltage on PIN1) is less than Power-Off Threshold (see in [Table 7](#)), but not less than -0.6 V. Another essential condition for the chip to be powered down is that no voltage higher (**Note**) than the V_{DD} voltage is applied to any other PIN. For example, if V_{DD} voltage is 0.3 V, applying a voltage higher than 0.3 V to any other PIN is incorrect, and can lead to incorrect or unexpected device behavior.

Note There is a 0.6 V margin due to forward drop voltage of the ESD protection diodes.

To start the POR sequence in the SLG47105, the voltage applied on the V_{DD} should be higher than the Power-On Threshold (**Note**). The full operational V_{DD} range for the SLG47105 is 2.3 V to 5.5 V. This means that the V_{DD} voltage must ramp up to the operational voltage value, but the POR sequence will start earlier, as soon as the V_{DD} voltage rises to the Power-On threshold. After the POR sequence is started, the SLG47105 will have a typical period of time to go through all the steps in the sequence (noted in the datasheet for that device) and will be ready and completely operational after the POR sequence is complete.

Note The Power-On Threshold is defined in [Table 7](#).

To power-down the chip the V_{DD} voltage should be lower than the operational and to guarantee that chip is powered down it should be less than Power-Off Threshold.

All PINs are in high impedance state when the chip is powered down and while the POR sequence is taking place. The last step in the POR sequence releases the IO structures from the high impedance state, at which time the device is operational. The pin configuration at this point in time is defined by the design programmed into the chip. Also, as it was mentioned before the voltage on PINs can't be bigger than the V_{DD} , this rule also applies to the case when the chip is powered on.

20.2 POR SEQUENCE

The POR system generates a sequence of signals that enable certain macrocells. The sequence is shown in [Figure 96](#).

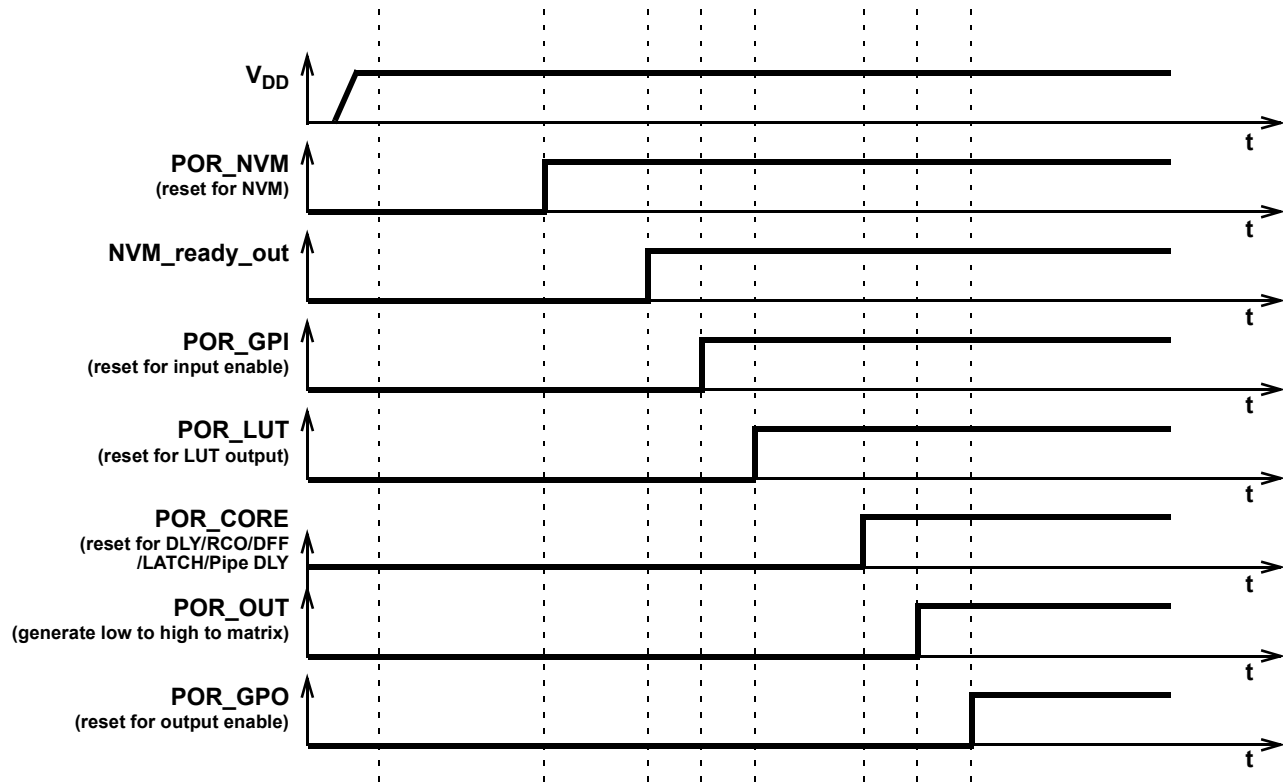

Figure 96: POR Sequence

As can be seen from [Figure 96](#) after the V_{DD} has started ramping up and crosses the Power-On threshold, first, the on-chip NVM memory is reset. Next, the chip reads the data from NVM and transfers this information to a CMOS LATCH, that serves to configure each macrocell, and the Connection Matrix, which routes signals between macrocells. The third stage causes the reset of the input pins, and then enables them. After that, the LUTs are reset and become active. After LUTs, the Delay cells, OSCs, DFFs, LATCHES, and Pipe Delay are initialized. Only after all macrocells are initialized internal POR signal (POR macrocell output) goes from LOW to HIGH. The last portion of the device to be initialized are the output pins, which transition from high impedance to active at this point.

The typical time that takes to complete the POR sequence varies by device type in the GreenPAK family. It also depends on many environmental factors, such as: slew rate, V_{DD} value, temperature, and even will vary from chip to chip (process influence).

20.3 MACROCELLS OUTPUT STATES DURING POR SEQUENCE

To have a full picture of SLG47105 operation during powering and POR sequence, review the overview the macrocell output states during the POR sequence (Figure 97 describes the output signals states).

First, before the NVM has been reset, all macrocells have their output set to logic LOW (except the output pins which are in high impedance state). On the next step, some of the macrocells start initialization: input pins output state becomes LOW; LUTs also output LOW. Only P_DLY macrocell configured as edge detector becomes active at this time. After that input pins are enabled. Next, only LUTs are configured. Next, all other macrocells are initialized. After macrocells are initialized, internal POR matrix signal switches from LOW to HIGH. The last are output pins that become active and determined by the input signals.

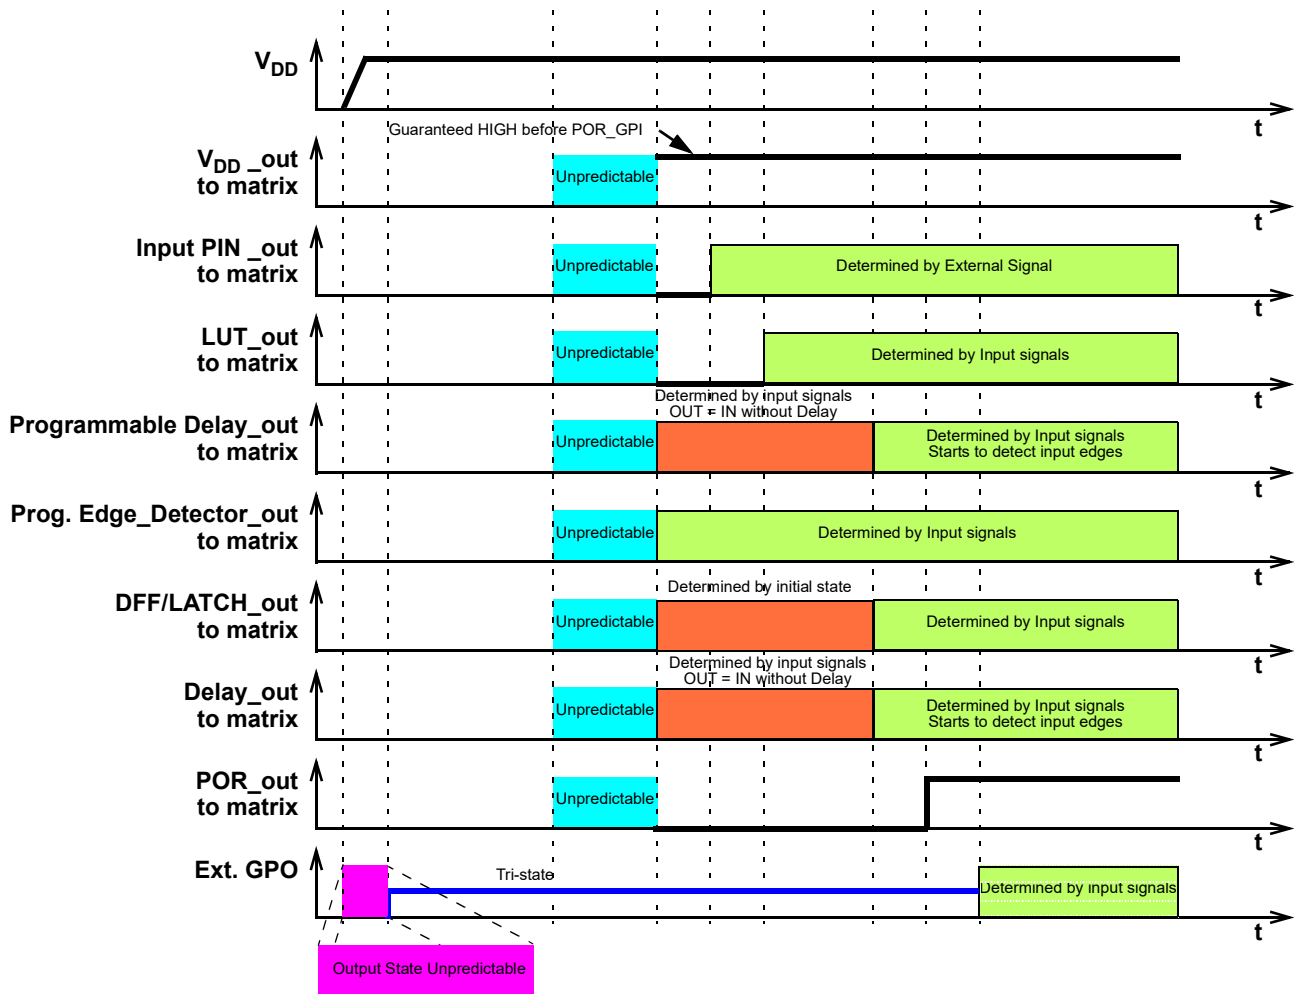

Figure 97: Internal Macrocell States During POR Sequence

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

20.3.1 Initialization

All internal macrocells by default have initial low level. Starting from indicated power-up time of , macrocells in SLG47105 are powered on while forced to the reset state. All outputs are in Hi-Z and chip starts loading data from NVM. Then the reset signal is released for internal macrocells and they start to initialize according to the following sequence:

- Input pins, ACMP, Pull-up/down.
- LUTs.
- DFFs, Delays/Counters, Pipe Delay.
- POR output to matrix.
- Output pin corresponds to the internal logic.

The Vref output pin driving signal can precede POR output signal going high by 3 μ s to 5 μ s. The POR signal going high indicates the mentioned power-up sequence is complete.

Note: The maximum voltage applied to any pin should not be higher than the V_{DD} level. There are ESD Diodes between pin $\rightarrow V_{DD}$ and pin \rightarrow GND on each pin. So, if the input signal applied to pin is higher than V_{DD} , then current will sink through the diode to V_{DD} . Exceeding V_{DD} results in leakage current on the input pin, and V_{DD} will be pulled up, following the voltage on the input pin. There is no effect from input pin when input voltage is applied at the same time as V_{DD} .

20.3.2 Power-Down

Figure 98: Power-Down

During Power-down, macrocells in SLG47105 are powered off after V_{DD} falling down below Power-Off Threshold. Please note that during a slow rampdown, outputs can possibly switch state during this time.

21 I²C Serial Communications Macrocell

21.1 I²C SERIAL COMMUNICATIONS MACROCELL OVERVIEW

In the standard use case for the GreenPAK devices, the configuration choices made by the user are stored as bit settings in the Non-Volatile Memory (NVM), and this information is transferred at startup time to volatile RAM registers that enable the configuration of the macrocells. Other RAM registers in the device are responsible for setting the connections in the Connection Matrix to route signals in the manner most appropriate for the user's application.

The I²C Serial Communications Macrocell in this device allows an I²C bus Master to read and write this information via a serial channel directly to the RAM registers, allowing the remote re-configuration of macrocells and remote changes to signal chains within the device.

The I²C bus Master is also able to read and write other register bits that are not associated with NVM memory. As an example, the input lines to the Connection Matrix can be read as digital register bits. These are the signal outputs of each of the macrocells in the device, giving the I²C bus Master the capability to remotely read the current value of any macrocell.

The user has the flexibility to control read access and write access via registers bits registers [1967:1965]. See Section 21.5.1 for more details on I²C read/write memory protection.

Normally, when V_{DD} is not applied, the external I²C Pull-up resistors can be connected to the I²C pins of the SLG47105. It does not affect the chip functionality and doesn't increase its current consumption.

21.2 I²C SERIAL COMMUNICATIONS DEVICE ADDRESSING

Each command to the I²C Serial Communications macrocell begins with a Control Byte. The bits inside this Control Byte are shown in Figure 99. After the Start bit, the first four bits are a control code. Each bit in a control code can be sourced independently from the register or by value defined externally by GPIO, GPIO6, GPIO4, and GPIO1. The LSB of the control code is defined by the value of GPIO, while the MSB is defined by the value of GPIO1. The address source (either register bit or PIN) for each bit in the control code is defined by registers [2027:2024]. This gives the user flexibility on the chip level addressing of this device and other devices on the same I²C bus. The Block Address is the next three bits (A10, A9, A8), which will define the most significant bits in the addressing of the data to be read or written by the command. The last bit in the Control Byte is the R/W bit, which selects whether a read command or write command is requested, with a "1" selecting for a Read command, and a "0" selecting for a Write command. This Control Byte will be followed by an Acknowledge bit (ACK), which is sent by this device to indicate successful communication of the Control Byte data.

In the I²C-bus specification and user manual, there are two groups of eight addresses (0000 xxx and 1111 xxx) that are reserved for the special functions, such as a system General Call address. If the user of this device chooses to set the Control Code to either "1111" or "0000" in a system with other slave device, please consult the I²C-bus specification and user manual to understand the addressing and implementation of these special functions, to ensure reliable operation.

In the read and write command address structure, there are a total of 11 bits of addressing, each pointing to a unique byte of information, resulting in a total address space of 2K bytes. Of this 2K byte address space, the valid addresses accessible to the I²C Macrocell on the SLG47105 are in the range from 0 (0x00) to 255 (0xFF). The MSB address bits (A10, A9, and A8) will be "0" for all commands to the SLG47105.

With the exception of the Current Address Read command, all commands will have the Control Byte followed by the Word Address. Figure 99 shows this basic command structure.

Figure 99: Basic Command Structure

21.3 I²C SERIAL GENERAL TIMING

General timing characteristics for the I²C Serial Communications macrocell are shown in Figure 100. Timing specifications can be found in the AC Characteristics section.

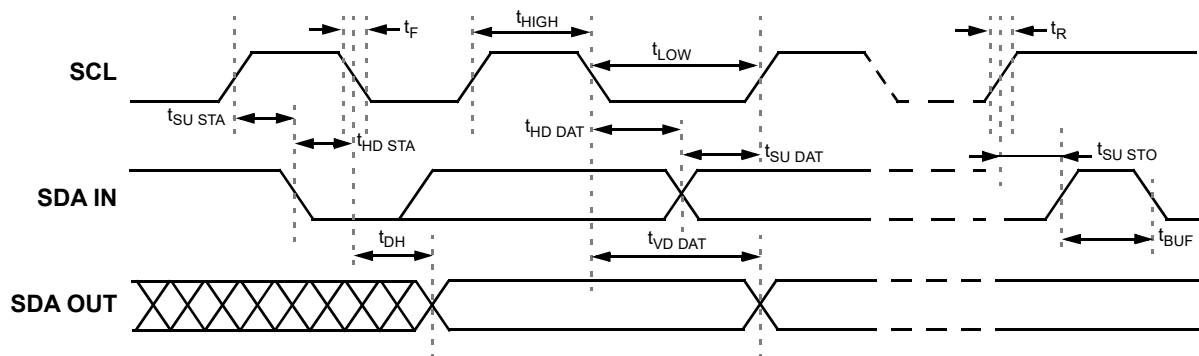

Figure 100: I²C General Timing Characteristics

21.4 I²C SERIAL COMMUNICATIONS COMMANDS

21.4.1 Byte Write Command

Following the Start condition from the Master, the Control Code [4 bits], the Block Address [3 bits], and the R/W bit (set to “0”) are placed onto the I²C bus by the Master. After the SLG47105 sends an Acknowledge bit (ACK), the next byte transmitted by the Master is the Word Address. The Block Address (A10, A9, A8), combined with the Word Address (A7 through A0), together set the internal address pointer in the SLG47105, where the data byte is to be written. After the SLG47105 sends another Acknowledge bit, the Master will transmit the data byte to be written into the addressed memory location. The SLG47105 again provides an Acknowledge bit and then the Master generates a Stop condition. The internal write cycle for the data will take place at the time that the SLG47105 generates the Acknowledge bit.

It is possible to LATCH all IOs during I²C write command, register [1961] = 1 - Enable. It means that IOs will remain their state until the write command is done.

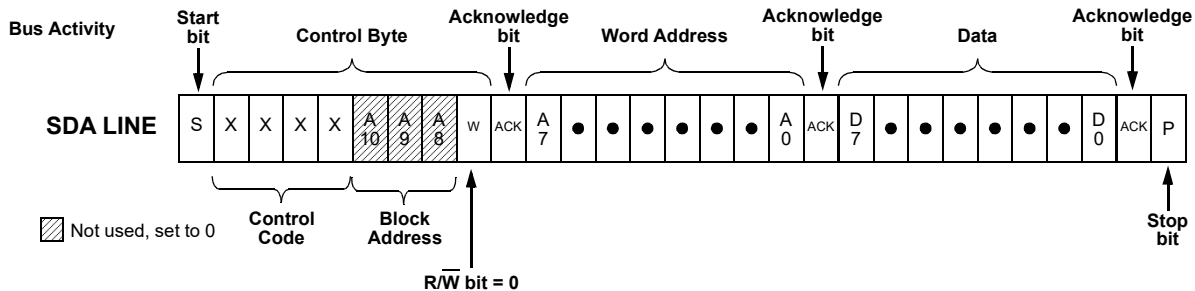

Figure 101: Byte Write Command, $R/\bar{W} = 0$

21.4.2 Sequential Write Command

The write Control Byte, Word Address, and the first data byte are transmitted to the SLG47105 in the same way as in a Byte Write command. However, instead of generating a Stop condition, the Bus Master continues to transmit data bytes to the SLG47105. Each subsequent data byte will increment the internal address counter, and will be written into the next higher byte in the command addressing. As in the case of the Byte Write command, the internal write cycle will take place at the time that the SLG47105 generates the Acknowledge bit.

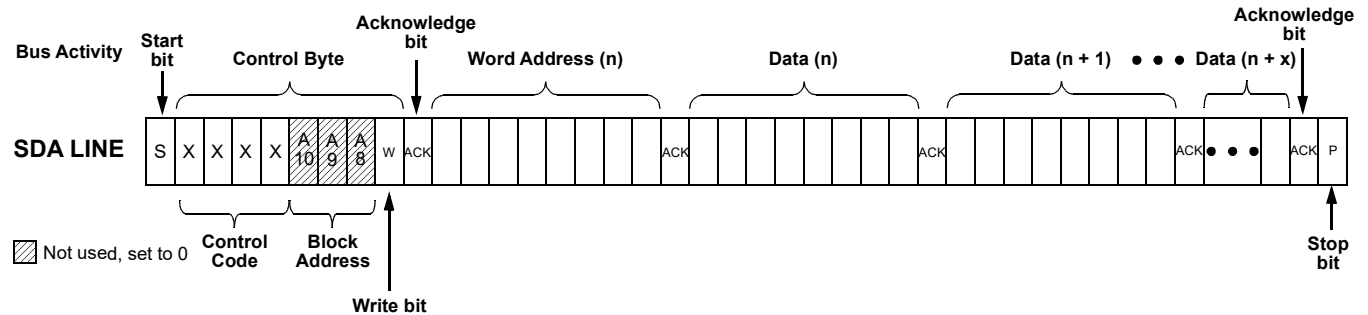

Figure 102: Sequential Write Command

21.4.3 Current Address Read Command

The Current Address Read Command reads from the current pointer address location. The address pointer is incremented at the first STOP bit following any write control byte. For example, if a Sequential Read command (which contains a write control byte) reads data up to address n, the address pointer would get incremented to n + 1 upon the STOP of that command. Subsequently, a Current Address Read that follows would start reading data at n + 1. The Current Address Read Command contains the Control Byte sent by the Master, with the R/\bar{W} bit = "1". The SLG47105 will issue an Acknowledge bit, and then transmit eight data bits for the requested byte. The Master will not issue an Acknowledge bit, and follow immediately with a Stop condition.

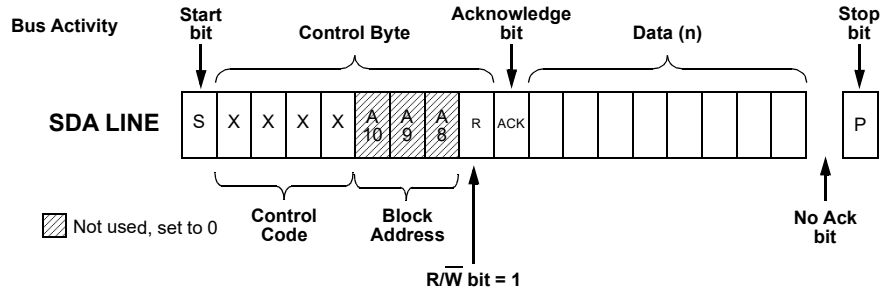

Figure 103: Current Address Read Command, $\overline{R/W} = 1$

21.4.4 Random Read Command

The Random Read command starts with a Control Byte (with R/W bit set to “0”, indicating a write command) and Word Address to set the internal byte address, followed by a Start bit, and then the Control Byte for the read (exactly the same as the Byte Write command). The Start bit in the middle of the command will halt the decoding of a Write command, but will set the internal address counter in preparation for the second half of the command. After the Start bit, the Bus Master issues a second control byte with the R/W bit set to “1”, after which the SLG47105 issues an Acknowledge bit, followed by the requested eight data bits.

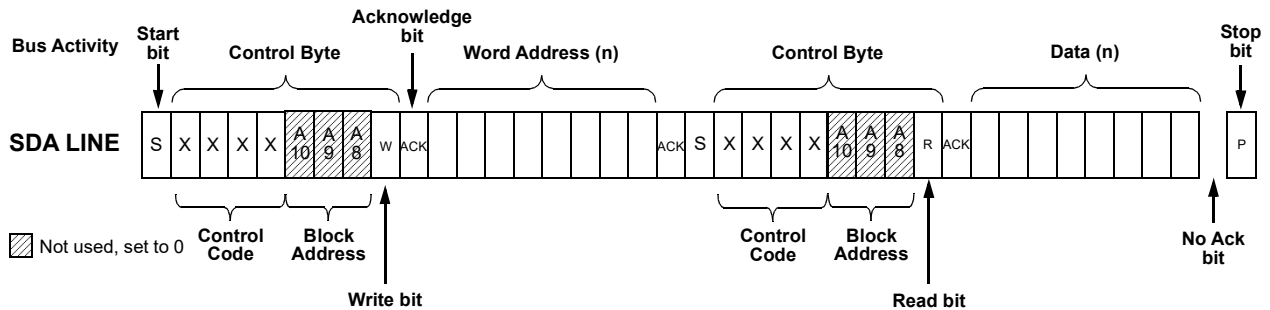

Figure 104: Random Read Command

21.4.5 Sequential Read Command

The Sequential Read command is initiated in the same way as a Random Read command, except that, once the SLG47105 transmits the first data byte, the Bus Master issues an Acknowledge bit as opposed to a Stop condition in a random read. The Bus Master can continue reading sequential bytes of data, and will terminate the command with a Stop condition.

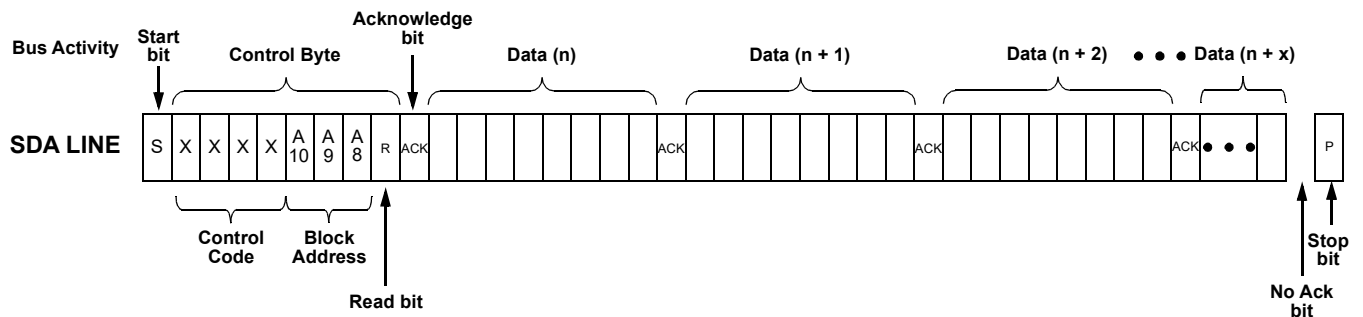

Figure 105: Sequential Read Command

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

21.5 I²C SERIAL COMMAND REGISTER MAP

21.5.1 Register Read/Write Protection

There are seven read/write protect modes for the design sequence from being corrupted or copied. See [Table 66](#) for details.

Table 66: Read/Write Protection Options

Configurations	Protection Modes Configuration							Data Output From	Register Address
	Unlocked	Partly Lock Read1	Partly Lock Read2	Partly Lock Read2/Write	Lock Read	Lock Write	Lock Read/Write		
	(Mode 0)	(Mode 1)	(Mode 2)	(Mode 3)	(Mode 4)	(Mode 5)	(Mode 6)		
I ² C Byte Write Bit Masking (section 21.5.5)	R/W	R/W	R/W	R/W	W	R	-	Memory	F6
I ² C Serial Reset Command (section 21.5.2)	R/W	R/W	R/W	R/W	W	R	-	Memory	F5,b'0
Outputs LATCHing During I ² C Write	R/W	R/W	R/W	R/W	W	R	-	Memory	F5,b'1
Connection Matrix Virtual Inputs (section 10.3)	R/W	R/W	R/W	R/W	W	R	-	Macrocell	4C
Configuration Bits for All Macrocells (IO Pins, ACMPs, Combination Function Macrocells, and others)	R/W	R/W	W	-	W	R	-	Memory	
Macrocells Inputs Configuration (Connection Matrix Outputs, section 10.2)	R/W	W	W	-	W	R	-	Memory	0~47
Protection Mode Enable	R	R	R	R	R	R	R	Memory	F5,b'4

Pin Slave Address Select	R	R	R	R	R	R	R	Memory	FD,b'7~4

Table 66: Read/Write Protection Options(Continued)

Configurations	Protection Modes Configuration							Data Output From	Register Address
	Unlocked	Partly Lock Read1	Partly Lock Read2	Partly Lock Read2/Write	Lock Read	Lock Write	Lock Read/Write		
	(Mode 0)	(Mode 1)	(Mode 2)	(Mode 3)	(Mode 4)	(Mode 5)	(Mode 6)		
I ² C Disable/Enable	R	R	R	R	R	R	R	Memory	FE,b'0

R/W	Allow Read and Write Data
W	Allow Write Data Only
R	Allow Read Data Only
-	The Data is protected for Read and Write

It is possible to read some data from macrocells, such as counter current value, connection matrix, and connection matrix virtual inputs. The I²C write will not have any impact on data in case data comes from macrocell output, except Connection Matrix Virtual Inputs. The silicon identification service bits allows identifying silicon family, its revision, and others.

See Section 23 for detailed information on all registers.

21.5.2 I²C Serial Reset Command

If I²C serial communication is established with the device, it is possible to reset the device to initial power up conditions, including configuration of all macrocells, and all connections provided by the Connection Matrix. This is implemented by setting register [1960] I²C reset bit to “1”, which causes the device to re-enable the Power-On Reset (POR) sequence, including the reload of all register data from NVM. During the POR sequence, the outputs of the device will be in tri-state. After the reset has taken place, the contents of register [1960] will be set to “0” automatically. Figure 106 illustrates the sequence of events for this reset function.

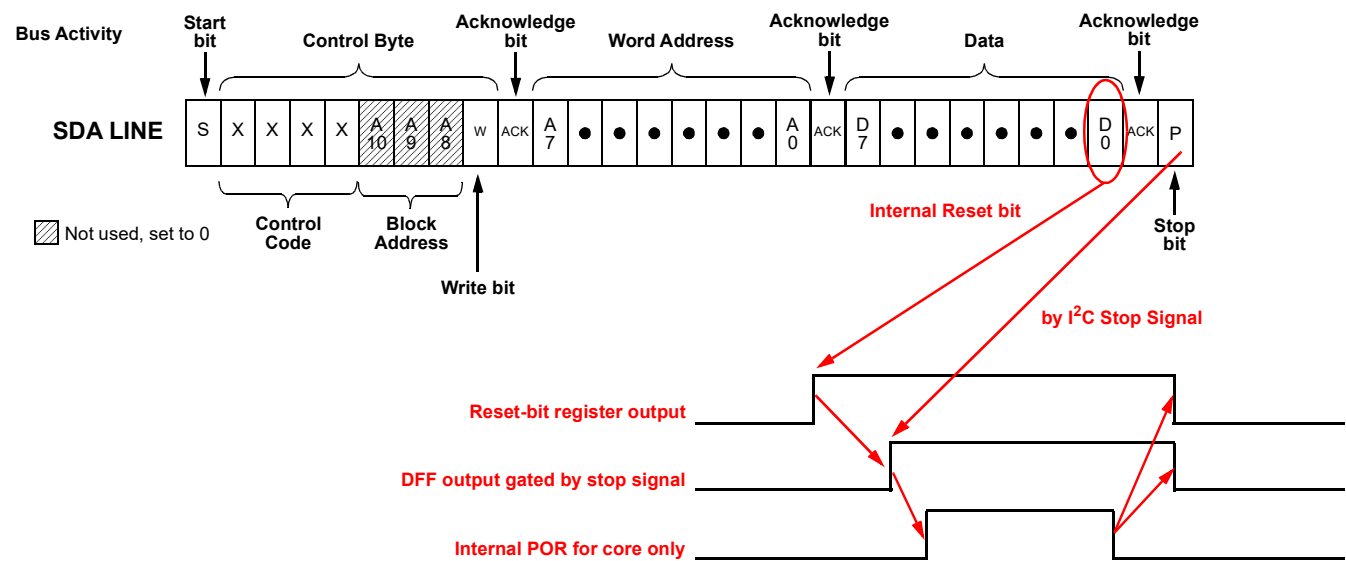

Figure 106: Reset Command Timing

21.5.3 I²C Additional Options

When Output latching during I²C write, register [1960] = 1 allows all PINs output value to be latched until I²C write is done. It will protect the output change due to configuration process during I²C write in case multiple register bytes are changed. Inputs and internal macrocells retain their status during I²C write.

If the user sets GPIO3 and GPIO2 function to a selection other than SDA and SCL, all access via I²C will be disabled.

Note: Any write commands that come to the device via I²C that are not blocked, based on the protection bits, will change the contents of the RAM register bits that mirror the NVM bits. These write commands will not change the NVM bits themselves, and a POR event will restore the register bits to original programmed contents of the NVM.

See Section 23 for detailed information on all registers.

21.5.4 Reading Current Counter Data via I²C

The current counter value in two counters in the device can be read via I²C. The counters that have this additional functionality are 16-bit CNT0 and 8-bit CNT4.

21.5.5 I²C Byte Write Bit Masking

The I²C macrocell inside SLG47105 supports masking of individual bits within a byte that is written to the RAM memory space. This function is supported across the entire RAM memory space. To implement this function, the user performs a Byte Write Command (see Section 21.4.1 for details) on the I²C Byte Write Mask Register (address 0F6H) with the desired bit mask pattern. This sets a bit mask pattern for the target memory location that will take effect on the next Byte Write Command to this register byte. Any bit in the mask that is set to "1" in the I²C Byte Write Mask Register will mask the effect of changing that particular bit in the target register, during the next Byte Write Command. The contents of the I²C Byte Write Mask Register are reset (set to 00h) after valid Byte Write Command. If the next command received by the device is not a Byte Write Command, the effect of the

bit masking function will be aborted, and the I²C Byte Write Mask Register will be reset with no effect. Figure 107 shows an example of this function.

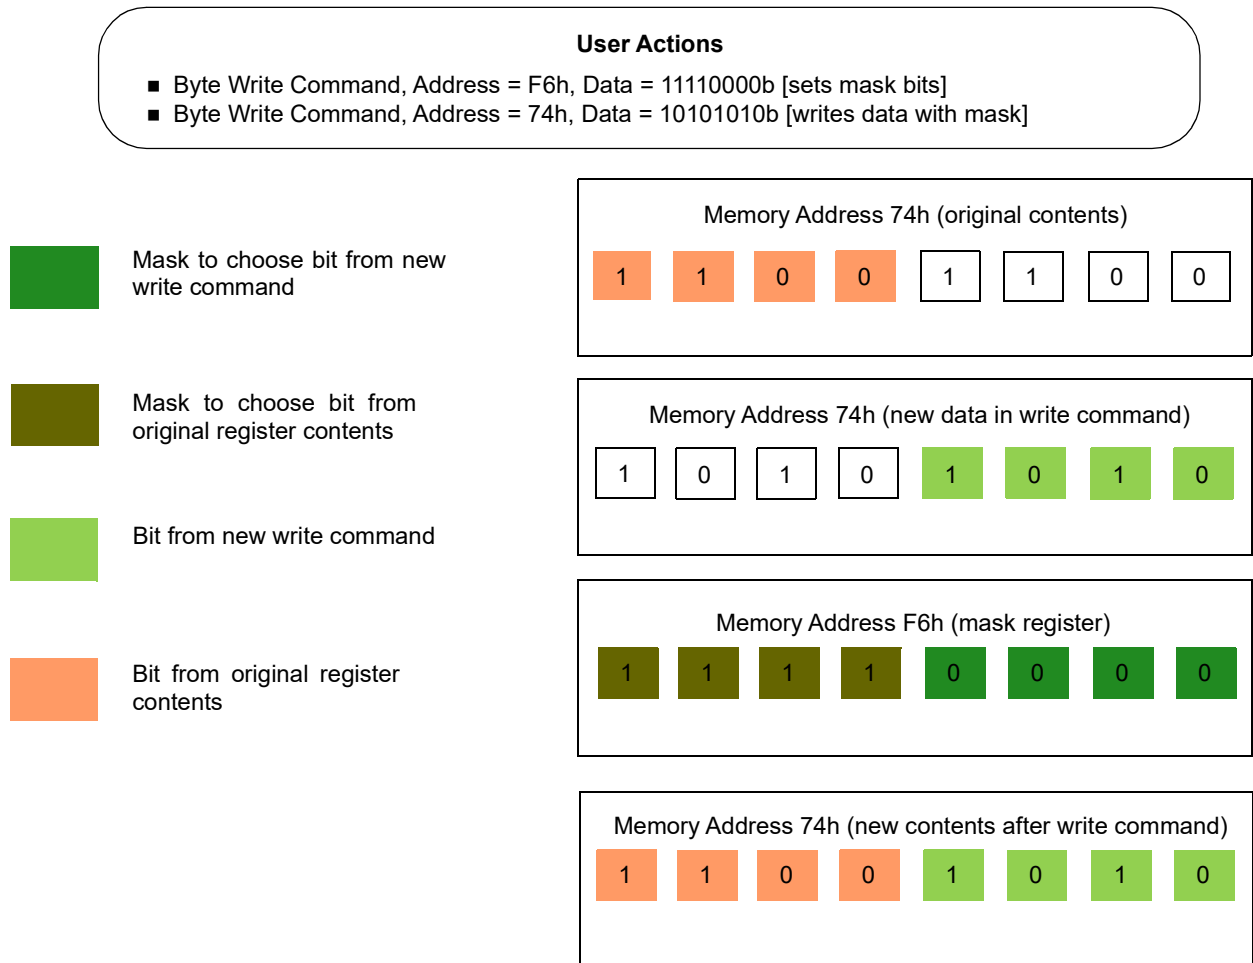

Figure 107: Example of I²C Byte Write Bit Masking

22 Analog Temperature Sensor

The SLG47105 has an Analog Temperature sensor (TS) with an output voltage linearly-proportional to the Centigrade temperature. The TS cell shares buffer with Vref0, so it is impossible to use both cells simultaneously, its output can be connected directly to the ACMP1_H positive input. The TS is rated to operate over a -40 °C to 150 °C junction temperature range. The error in the whole temperature range does not exceed ±1.7 %. For more details refer to Section 3.14.

The equation below calculates the typical analog voltage passed from the TS to the ACMPs' IN+ source input. It is important to note that there will be a chip to chip variation of about ±2 °C.

$$V_{TS1} = -2.4 \times T + 912.3$$

$$V_{TS2} = -2.9 \times T + 1101.3$$

where:

V_{TS1} (mV) - TS Output Voltage, range 1

V_{TS2} (mV) - TS Output Voltage, range 2

T (°C) - Temperature

Temperature hysteresis can be setup by enabling the GreenPAK's internal ACMP hysteresis.

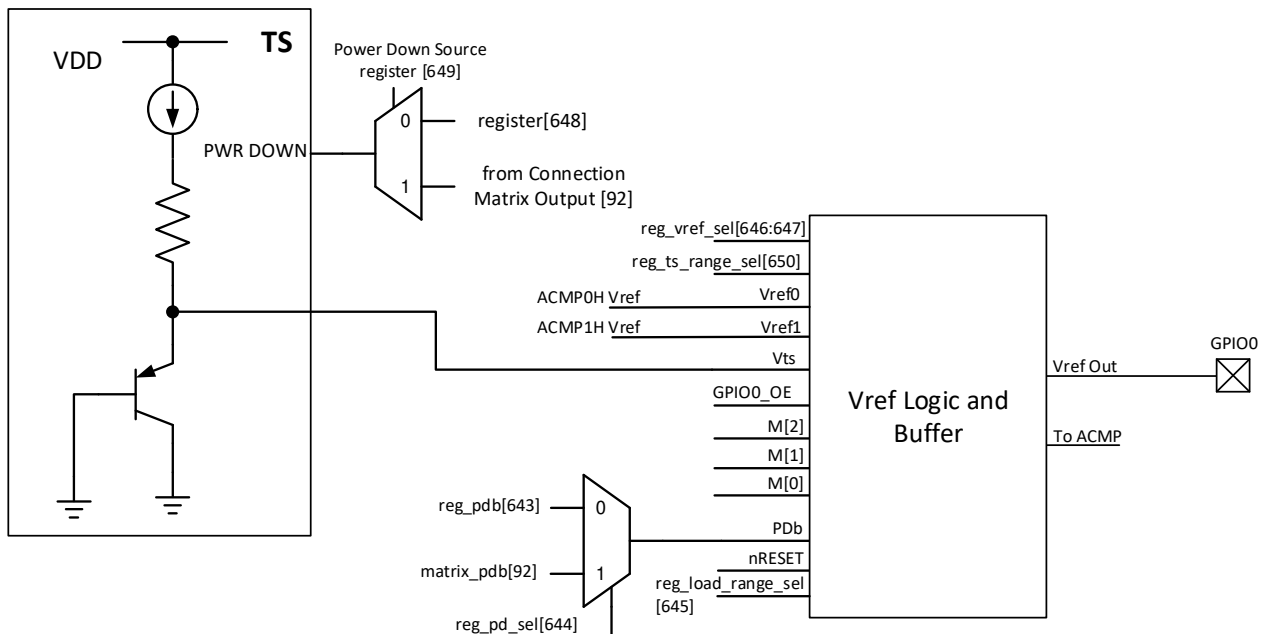

Figure 108: Analog Temperature Sensor Structure Diagram

Figure 109: TS Output vs. Temperature, $V_{DD} = 2.3\text{ V to }5.5\text{ V}$

25 Package Information

25.1 PACKAGE OUTLINES FOR STQFN 20L 2 MM X 3 MM 0.4P FCD GREEN PACKAGE

Notes:

1. All dimensions are in millimeters.
2. Dimension "b" applies to metalized terminal and is measured between 0.15 mm and 0.30 mm from the terminal tip. If the terminal has the optional radius on the other end of the terminal, the dimension "b" should not be measured in that radius area.
3. Bilateral coplanarity zone applies to the exposed heat sink as well as the terminal.

Controlling dimension: mm

25.2 MOISTURE SENSITIVITY LEVEL

The Moisture Sensitivity Level (MSL) is an indicator for the maximum allowable time period (floor lifetime) in which a moisture sensitive plastic device, once removed from the dry bag, can be exposed to an environment with a specified maximum temperature and a maximum relative humidity before the solder reflow process. The MSL classification is defined in [Table 68](#).

For detailed information on MSL levels refer to the IPC/JEDEC standard J-STD-020, which can be downloaded from <http://www.jedec.org>.

The [PACKAGE_NAME] package is qualified for MSL [n].

Table 68: MSL Classification

MSL Level	Floor Lifetime	Conditions
MSL 4	72 hours	30 °C / 60 % RH
MSL 3	168 hours	30 °C / 60 % RH
MSL 2A	4 weeks	30 °C / 60 % RH
MSL 2	1 year	30 °C / 60 % RH
MSL 1	Unlimited	30 °C / 60 % RH

25.3 SOLDERING INFORMATION

Refer to the IPC/JEDEC standard J-STD-020 for relevant soldering information. This document can be downloaded from www.jedec.org.

26 Ordering Information

Table 69: Ordering Information

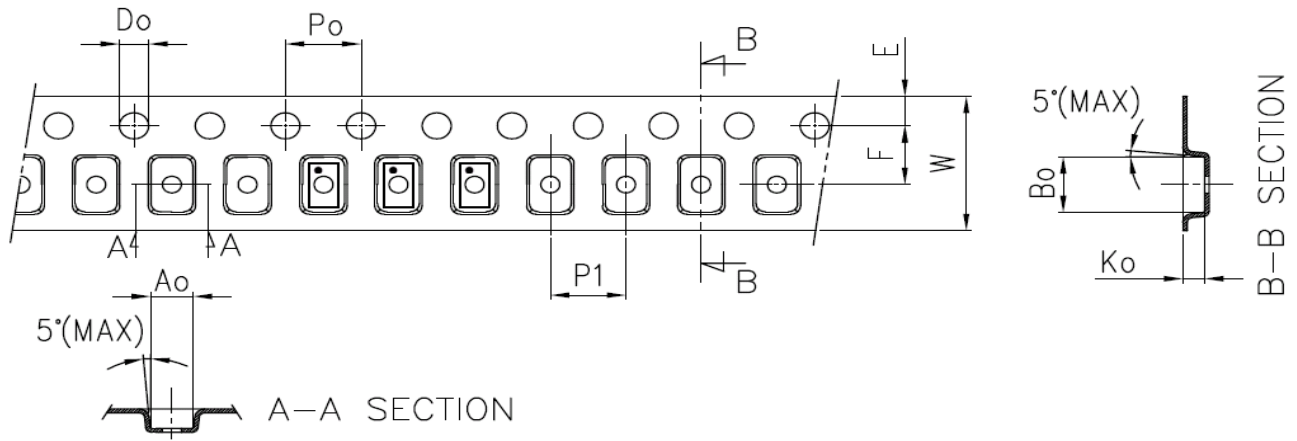

Part Number	Type
SLG47105V	20-pin STQFN
SLG47105VTR	20-pin STQFN - Tape and Reel (3k units)

STQFN 20L 2 mm x 3 mm 0.4P FCD Green	2.2	3.15	0.76	4	4	1.5	1.75	3.5	8

27 Thermal Guidelines

Actual thermal characteristics will depend on number and position of vias, PCB type, copper layers, and other factors. Operating temperature range is from $-40\text{ }^{\circ}\text{C}$ to $85\text{ }^{\circ}\text{C}$. To guarantee reliable operation, the junction temperature of the SLG47105 must not exceed $150\text{ }^{\circ}\text{C}$.

To avoid overheating of the power MOSFETs (as shown in Figure 109), a good thermal design of the PCB layout must be implemented, especially when device operates near its maximum thermal limits. Refer to Section 3.4 to find max value of Thermal Resistance.

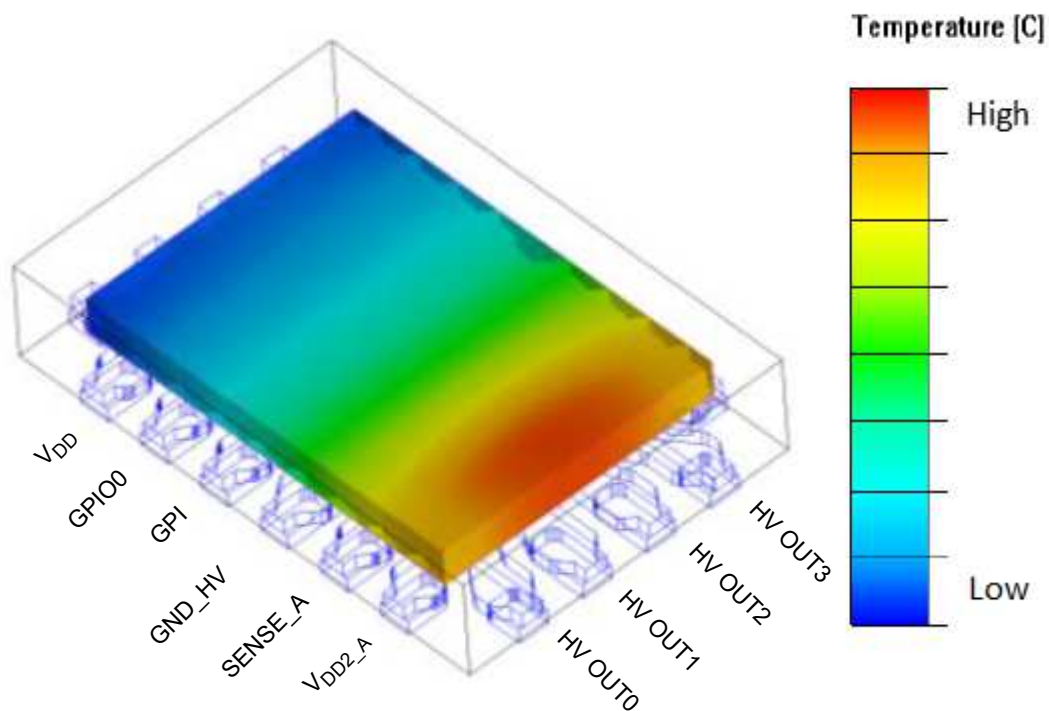

Figure 111: Die Temperature when HV OUTs are Active

28 Layout consideration

PCB should have enough ground plane to dissipate heat. SLG47105 has two additional pads which provide enhanced thermal dissipation. Thermal vias are used to transfer heat from chip to other layers of the PCB.

The sense resistors and power capacitors should be placed as close as possible to the chip for reducing parasitic parameters.

Typical Application Circuit is shown in [Figure 112](#).

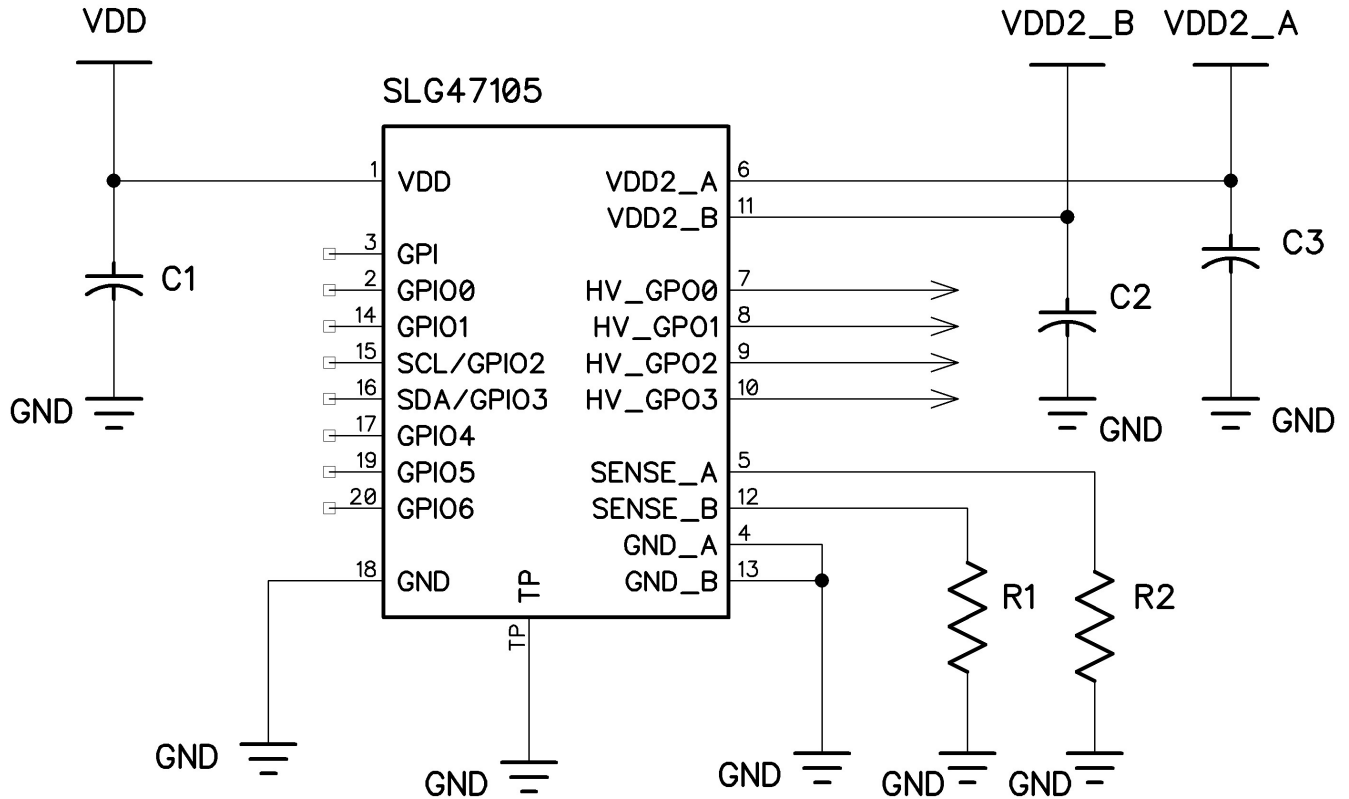

Figure 112: Typical Application Circuit

Figure 113: PCB Layout Example

29 Layout Guidelines

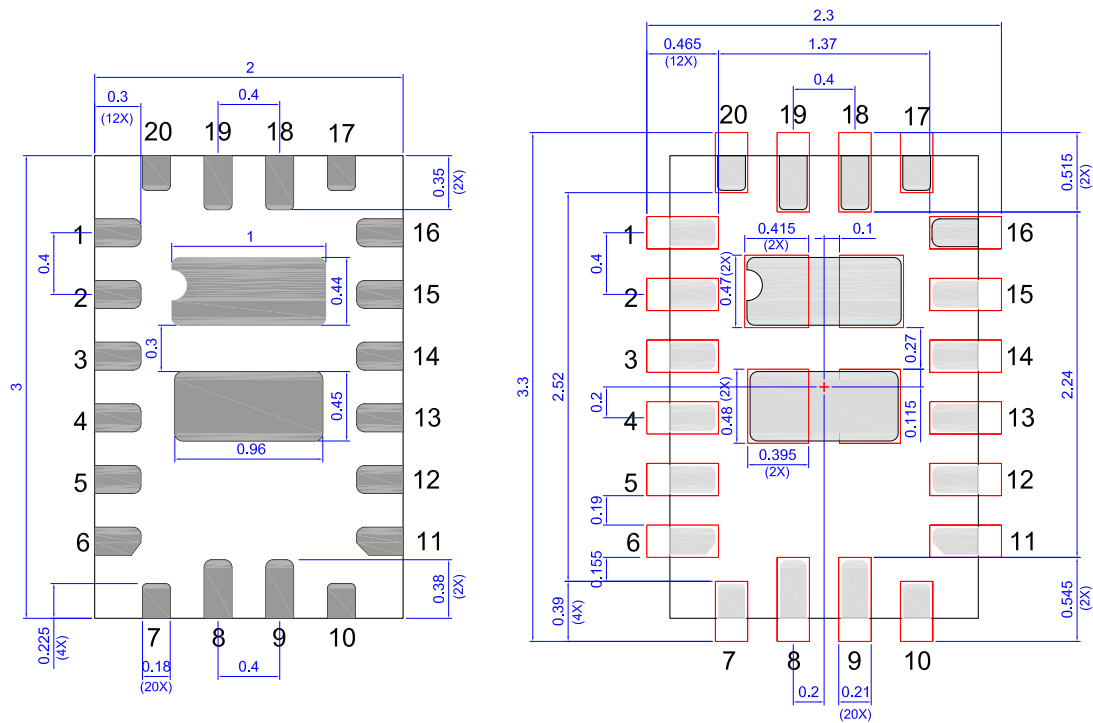

29.1 STQFN 20L 2 MM X 3.0 MM X 0.55 MM 0.4P FCD PACKAGE

It's highly recommended to place low-ESR capacitor between V_{DD2_A} , V_{DD2_B} , and GND pin to keep input voltage stable and reduce ripple. This capacitor should be placed as close to the pins as possible. Also, the capacitor must have the low input impedance at the switching frequency. The recommended value of this capacitor is 1-10 μF for most applications. Motors with larger armature inductors require larger input capacitors.

Also, it's highly recommended to place 0.1 μF ceramic capacitor between V_{DD} and GND.

GreenPAK Programmable Mixed-Signal Matrix with High Voltage Features

Preliminary

Status Definitions

Revision	Datasheet Status	Product Status	Definition
1.<n>	Target	Development	This datasheet contains the design specifications for product development. Specifications may change in any manner without notice.
2.<n>	Preliminary	Qualification	This datasheet contains the specifications and preliminary characterization data for products in pre-production. Specifications may be changed at any time without notice in order to improve the design.
3.<n>	Final	Production	This datasheet contains the final specifications for products in volume production. The specifications may be changed at any time in order to improve the design, manufacturing and supply. Major specification changes are communicated via Customer Product Notifications. Datasheet changes are communicated via www.dialog-semiconductor.com .
4.<n>	Obsolete	Archived	This datasheet contains the specifications for discontinued products. The information is provided for reference only.

Disclaimer

Unless otherwise agreed in writing, the Dialog Semiconductor products (and any associated software) referred to in this document are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of a Dialog Semiconductor product (or associated software) can reasonably be expected to result in personal injury, death or severe property or environmental damage. Dialog Semiconductor and its suppliers accept no liability for inclusion and/or use of Dialog Semiconductor products (and any associated software) in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Information in this document is believed to be accurate and reliable. However, Dialog Semiconductor does not give any representations or warranties, express or implied, as to the accuracy or completeness of such information. Dialog Semiconductor furthermore takes no responsibility whatsoever for the content in this document if provided by any information source outside of Dialog Semiconductor.

Dialog Semiconductor reserves the right to change without notice the information published in this document, including, without limitation, the specification and the design of the related semiconductor products, software and applications. Notwithstanding the foregoing, for any automotive grade version of the device, Dialog Semiconductor reserves the right to change the information published in this document, including, without limitation, the specification and the design of the related semiconductor products, software and applications, in accordance with its standard automotive change notification process.

Applications, software, and semiconductor products described in this document are for illustrative purposes only. Dialog Semiconductor makes no representation or warranty that such applications, software and semiconductor products will be suitable for the specified use without further testing or modification. Unless otherwise agreed in writing, such testing or modification is the sole responsibility of the customer and Dialog Semiconductor excludes all liability in this respect.

Nothing in this document may be construed as a license for customer to use the Dialog Semiconductor products, software and applications referred to in this document. Such license must be separately sought by customer with Dialog Semiconductor.

All use of Dialog Semiconductor products, software and applications referred to in this document is subject to Dialog Semiconductor's [Standard Terms and Conditions of Sale](http://www.dialog-semiconductor.com), available on the company website (www.dialog-semiconductor.com) unless otherwise stated.

RoHS Compliance

Dialog Semiconductor's suppliers certify that its products are in compliance with the requirements of Directive 2011/65/EU of the European Parliament on the restriction of the use of certain hazardous substances in electrical and electronic equipment. RoHS certificates from our suppliers are available on request.
