

1.5MHz Synchronous Dual Channel DC/DC Converter and 100mA LDO

FEATURES

- **Extremely Compact Triple-Rail Solution**
- **Burst Mode® Operation, $I_Q = 15\mu A$**
- **1.5MHz Fixed Frequency Operation**
- Power Good Indicators
- **700mA Synchronous Step-Up DC/DC**
 - 0.65V to 5V V_{IN} Range
 - 1.5V to 5.25V V_{OUT} Range
 - 94% Peak Efficiency
 - $V_{IN} > V_{OUT}$ Operation
 - Output Disconnect
- **250mA Synchronous Step-Down DC/DC**
 - 1.8V to 5.5V V_{IN} Range
 - 0.6V to 5.5V V_{OUT} Range
- **LDO (V_{IN} Internally Tied to V_{BST})**
 - 0.6V to 5.25V V_{OUT} Range
 - 200mV Dropout Voltage at 100mA
- Available in a 16-Lead 3mm × 3mm QFN Package

APPLICATIONS

- Bar Code Readers
- Medical Instruments
- Low Power Portable Electronic Devices

DESCRIPTION

The LTC3100 combines a high efficiency 700mA synchronous step-up converter, a 250mA synchronous step-down converter and a 100mA LDO regulator. The LTC3100 features a wide input voltage range of 0.65V to 5V. The step-down converter can be powered by the output of the step-up converter or from a separate power source between 1.8V and 5.5V. The LDO can also be used as a sequencing switch on the output of the boost.

A switching frequency of 1.5MHz minimizes solution footprint by allowing the use of tiny, low profile inductors and ceramic capacitors. The switching regulators use current mode control and are internally compensated, reducing external parts count. Each converter automatically transitions to Burst Mode operation to maintain high efficiency over the full load range. Burst Mode operation can be disabled for low noise applications. The integrated LDO provides a third low noise, low dropout supply.

Anti-ringing circuitry reduces EMI by damping the boost inductor in discontinuous mode. Additional features include shutdown current of under $1\mu A$ and overtemperature shutdown. The LTC3100 is housed in a 16-lead 3mm × 3mm 0.75mm QFN package.

LT, LTC, LTM and Burst Mode are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

TYPICAL APPLICATION

Efficiency and Power Loss vs Load Current, $V_{IN} = 2.4V$

ABSOLUTE MAXIMUM RATINGS

(Note 1)

V_{INBST} and V_{INBK} Voltage	–0.3 to 6V
SWBST, SWBK DC Voltage	–0.3 to 6V
SWBST, SWBK Pulsed (< 100ns) Voltage	–0.3 to 7V
FBBST, FBBK, FBLDO, PGBST, PGBK Voltage ..	–0.3 to 6V
MODE, RUNBST, RUNBK, RUNLDO Voltage...	–0.3 to 6V
V_{BST} , V_{LDO}	–0.3 to 6V
Operating Temperature (Notes 2, 5)	–40°C to 85°C
Storage Temperature Range	–65°C to 125°C

ELECTRICAL CHARACTERISTICS

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The LTC3100E is guaranteed to meet performance specifications from 0°C to 85°C. Specifications over -40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls.

Note 3: Specification is guaranteed by design and not 100% tested in production.

Note 4: Current measurements are made when the output is not switching.

Note 5: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed 125°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may result in device degradation or failure.

Note 6: Failure to solder the exposed backside of the package to the PC board ground plane will result in a thermal resistance much higher than 68°C/W.

PIN FUNCTIONS

SWBST (Pin 1): Switch Pin for the Boost Converter. Connect the boost inductor between SWBST and V_{INBST} . Keep PCB trace lengths as short and wide as possible to reduce EMI. If the inductor current falls to zero, an internal anti-ringing switch is connected from SWBST to V_{INBST} to minimize EMI.

V_{BST} (Pin 2): Output Voltage for the Boost Converter (which is the drain of the internal synchronous rectifier) and Input Voltage for the LDO. PCB trace length from V_{BST} to the output filter capacitor (10 μF minimum) should be as short and wide as possible.

V_{LDO} (Pin 3): Output Voltage of the LDO Regulator. Connect a 1 μF ceramic capacitor between V_{LDO} and GND. Larger values of capacitance may be used for higher PSRR or improved transient response.

SWBK (Pin 4): Switch Pin for the Buck Converter. Connect the buck inductor between SWBK and the buck output filter capacitor. Keep PCB trace lengths as short and wide as possible to reduce EMI.

V_{INBK} (Pin 5): Input Voltage for the Buck Converter. Connect a minimum of 4.7 μF ceramic decoupling capacitor from this pin to ground.

PGBK (Pin 6): Open-Drain Output That Pulls Low When FBBK Is More Than 8% Below Its Regulated Voltage. Con-

nect a pull-up resistor from this pin to a positive supply less than 6V.

GND (Pin 7): Signal Ground. Provide a short, direct PCB path between GND and the PC board ground plane connected to the Exposed Pad.

RUNBK (Pin 8): Logic-Controlled Shutdown Input for the Buck Converter. There is an internal 4M Ω pull-down on this pin.

RUNBK = High: Normal operation

RUNBK = Low: Shutdown

FBBK (Pin 9): Feedback Input to the g_m Error Amplifier for the Buck Converter. Connect the resistor divider tap to this pin. The output voltage can be adjusted from 0.6V to 5.5V by:

$$V_{OUT_BUCK} = 0.600V \cdot \left(1 + \frac{R_6}{R_5} \right)$$

RUNLDO (Pin 10): Logic-Controlled Shutdown Input for the LDO Regulator. There is an internal 4M Ω pull-down on this pin.

RUNLDO = High: Normal operation

RUNLDO = Low: Shutdown

PIN FUNCTIONS

FBLDO (Pin 11): Feedback Input to the g_m Error Amplifier for the LDO Regulator. Connect the resistor divider tap to this pin. The output voltage can be adjusted from 0.6V to 5.25V by:

$$V_{OUT_LDO} = 0.600V \cdot \left(1 + \frac{R4}{R3}\right)$$

FBBST (Pin 12): Feedback Input to the g_m Error Amplifier for the Boost Converter. Connect the resistor divider tap to this pin. The output voltage can be adjusted from 1.5V to 5.25V by:

$$V_{OUT_BOOST} = 1.20V \cdot \left(1 + \frac{R2}{R1}\right)$$

MODE (Pin 13): Logic-Controlled Mode Select Pin for Both the Boost and Buck Converters. There is an internal $1M\Omega$ pull-up on this pin to the higher of V_{INBST} , V_{BST} or V_{INBK} .

MODE = Float or High: Enables Burst Mode operation for both the boost and the buck.

MODE = Low: Disables Burst Mode operation. Both converters will operate in fixed frequency mode regardless of load current.

RUNBST (Pin 14): Logic-Controlled Shutdown Input for the Boost Converter. There is an internal $4M\Omega$ pull-down on this pin.

RUNBST = High: Normal operation

RUNBST = Low: Shutdown

PGBST (Pin 15): Open-Drain Output That Pulls to Ground When FBBST Is More Than 8% Below Its Regulated Voltage. Connect a pull-up resistor from this pin to a positive supply less than 6V.

V_{INBST} (Pin 16): Input Voltage for the Boost Converter. Connect a minimum of $1\mu F$ ceramic decoupling capacitor from this pin to ground.

Exposed Pad (Pin 17): The Exposed Pad **must** be soldered to the PCB ground plane. It serves as the power ground connection, and as a means of conducting heat away from the die.

BLOCK DIAGRAM

OPERATION

The LTC3100 includes an 700mA synchronous step-up (boost) converter, a 250mA synchronous step-down (buck) converter and a 100mA low dropout (LDO) linear regulator housed in a 16-lead 3mm × 3mm QFN package. Both converters utilize current mode PWM control for exceptional line and load regulation and operate from the same 1.5MHz oscillator. The current mode architecture with adaptive slope compensation also provides excellent transient load response, requiring minimal output filtering. Both converters have internal soft-start and internal loop compensation, simplifying the design process and minimizing the number of external components.

With its low $R_{DS(ON)}$ and low gate charge internal MOSFET switches and synchronous rectifiers, the LTC3100 achieves high efficiency over a wide range of load current. Burst Mode operation maintains high efficiency at very light loads, but can be disabled for noise-sensitive applications.

With separate power inputs for the boost and buck converters, along with independent enable and power good functions, the LTC3100 is very flexible. The two converters can operate from the same input supply, or from two different sources, or can even be cascaded by powering the buck converter from the output of the boost converter. By using the LDO as well, three different output voltages can be generated from a single alkaline/NiMH cell (or the LDO can be used for power sequencing the boost output).

Operation can be best understood by referring to the Block Diagram.

BOOST CONVERTER

Low Voltage Start-Up

The LTC3100 boost converter includes an independent start-up oscillator designed to start up at an input voltage of 0.65V (typical). Soft-start and inrush current limiting are provided during start-up, as well as in normal mode.

When either V_{INBST} or V_{BST} exceeds 1.4V (typical), the IC enters normal operating mode. Once the output voltage exceeds the input by 0.24V, the IC powers itself from V_{BST} instead of V_{INBST} . At this point, the internal circuitry has no dependency on the input voltage, eliminating the

requirement for a large input capacitor. The limiting factor for the application becomes the ability of the power source to supply sufficient energy to the output at low input voltages, and maximum duty cycle of the converter, which is clamped at 90% (typical). Note that at low input voltages, even small input voltage drops due to series resistance become critical, and greatly limit the power delivery capability of the converter.

LOW NOISE FIXED FREQUENCY OPERATION

Soft-Start

The internal soft-start circuitry ramps the peak boost inductor current from zero to its peak value of 700mA in approximately 800μs, allowing start-up into heavy loads. The soft-start circuitry is reset in the event of a commanded shutdown or an overtemperature shutdown.

Oscillator

An internal oscillator sets the switching frequency to 1.5MHz. The oscillator allows a maximum duty cycle of 90% (typical) for the boost converter.

Shutdown

The boost converter is shut down by pulling the RUNBST pin below 0.3V, and activated by pulling the RUNBST pin above 0.9V. Note that RUNBST can be driven above V_{IN} or V_{OUT} , as long as it is limited to less than the absolute maximum rating.

Error Amplifier

The error amplifier is a transconductance type. The non-inverting input is internally connected to the 1.20V reference and the inverting input is connected to FBBST. Clamps limit the minimum and maximum error amp output voltage for improved large signal transient response. Power converter control loop compensation is provided internally. A voltage divider from V_{BST} to ground programs the output voltage (via FBBST) from 1.5V to 5.25V, according to the formula:

$$V_{BST} = 1.20V \cdot \left(1 + \frac{R2}{R1} \right)$$

OPERATION

Current Sensing

Lossless current sensing converts the peak current signal of the N-channel MOSFET switch into a voltage which is summed with the internal slope compensation. The summed signal is compared to the error amplifier output to provide a peak current control command for the PWM.

Current Limit

The current limit comparator shuts off the N-channel MOSFET switch once its threshold is reached. Peak switch current is no less than 700mA, independent of input or output voltage, unless V_{OUT} falls below 1V, in which case the current limit is cut in half to minimize power dissipation into a short-circuit.

Slope Compensation

Current mode control requires the use of slope compensation to prevent subharmonic oscillations in the inductor current waveform at high duty cycle operation. This is accomplished internally on the LTC3100 through the addition of a compensating ramp to the current sense signal. The LTC3100 performs current limiting prior to addition of the slope compensation ramp and therefore achieves a peak inductor current limit that is independent of duty cycle.

Zero Current Comparator

The zero current comparator monitors the boost inductor current to the output and shuts off the synchronous rectifier once this current reduces to approximately 30mA. This prevents the inductor current from reversing in polarity, improving efficiency at light loads.

Synchronous Rectifier

To control inrush current and to prevent the inductor current from running away when V_{OUT} is close to V_{IN} , the P-channel MOSFET synchronous rectifier is only fully enabled when $V_{OUT} > (V_{IN} + 0.24V)$.

Anti-Ringing Control

The anti-ring circuitry connects a resistor across the boost inductor to prevent high frequency ringing on the

SW pin during discontinuous current mode operation. The ringing of the resonant circuit formed by L and C_{SW} (capacitance on SWBST pin) is low energy, but can cause EMI radiation.

PGOOD Comparator

The PGBST pin is an open-drain output which indicates the status of the boost converter output voltage. If the boost output voltage falls 8% below the regulation voltage, the PGBST open-drain output will pull low. The output voltage must rise 3% above the falling threshold before the pull-down will turn off. In addition, there is a 60 μ s (typical) deglitching delay in order to prevent false trips due to voltage transients on load steps. The PGBST output will also pull low if the boost converter is disabled. The typical PGBST pull-down switch resistance is 13 Ω when V_{BST} or V_{INBST} equals 3.3V.

Output Disconnect

The LTC3100 boost converter is designed to allow true output disconnect by eliminating body diode conduction of the internal P-channel MOSFET rectifier. This allows for V_{OUT} to go to 0V during shutdown, drawing no current from the input source. It also allows for inrush current limiting at turn-on, minimizing surge currents seen by the input supply. Note that to obtain the advantages of output disconnect, there must not be an external Schottky diode connected between SWBST and V_{BST} . The output disconnect feature also allows V_{OUT} to be pulled high without any reverse current into the battery.

$V_{IN} > V_{OUT}$ Operation

The LTC3100 boost converter will maintain voltage regulation even when the input voltage is above the desired output voltage. Note that the output current capability is slightly reduced in this mode of operation. Refer to the Typical Performance Characteristics section.

Burst Mode Operation (for Boost and Buck Converters)

Burst Mode operation for both converters can be enabled or disabled using the MODE pin. If MODE is grounded, Burst Mode operation is disabled for both the boost and

OPERATION

buck converters. In this case, both converters will remain in fixed frequency operation, even at light load currents. If the load is very light, they will exhibit pulse-skip operation.

If MODE is raised above 0.9V, or left open, Burst Mode operation will be enabled for both converters. In this case, either converter may enter Burst Mode operation at light load, and return to fixed frequency operation when the load current increases. Refer to the Typical Performance Characteristics section to see the output load Burst Mode threshold vs V_{IN} and V_{OUT} . The two converters can enter or leave Burst Mode operation independent of each other.

In Burst Mode operation, each converter still switches at a frequency of 1.5MHz, using the same error amplifier and loop compensation for peak current mode control. This control method eliminates any output transient when switching between modes. In Burst Mode operation, energy is delivered to the output until it reaches the nominal regulation value, then the LTC3100 transitions to sleep mode where the outputs are off and the LTC3100 consumes only 15 μ A of quiescent current from V_{BST} . Once the output voltage has drooped slightly, switching resumes again. This maximizes efficiency at very light loads by minimizing switching and quiescent losses. Burst Mode operation output ripple is typically 1% peak-to-peak.

Burst Mode operation for the boost converter is inhibited during start-up, and until soft-start is complete and V_{BST} is at least 0.24V greater than V_{INBST} .

Short-Circuit Protection

The LTC3100 output disconnect feature allows output short-circuit while maintaining a maximum internally set current limit. To reduce power dissipation under short-circuit conditions, the boost peak switch current limit is reduced to 400mA (typical).

Schottky Diode

Although it is not required, adding a Schottky diode from SWBST to V_{BST} will improve efficiency by about 2%. Note that this defeats the boost output disconnect and short-circuit protection features.

BUCK CONVERTER OPERATION

The buck converter provides a high efficiency, lower voltage output and supports 100% duty cycle operation to extend battery life. The buck converter uses the same 1.5MHz oscillator used by the boost converter.

PWM Mode Operation

When the MODE pin is held low, the LTC3100 buck converter uses a constant-frequency, current mode control architecture. Both the main (P-channel MOSFET) and synchronous rectifier (N-channel MOSFET) switches are internal. At the start of each oscillator cycle, the P-channel switch is turned on and remains on until the current waveform with superimposed slope compensation ramp exceeds the error amplifier output. At this point, the synchronous rectifier is turned on and remains on until the inductor current falls to zero or a new switching cycle is initiated. As a result, the buck converter operates with discontinuous inductor current at light loads which improves efficiency. At extremely light loads, the minimum on-time of the main switch will be reached and the buck converter will begin turning off for multiple cycles (pulse-skipping) in order to maintain regulation.

Burst Mode Operation

When the MODE pin is forced high, or left open, the buck converter will automatically transition between Burst Mode operation at sufficiently light loads (below approximately 10mA) and PWM mode at heavier loads. Burst Mode operation entry is determined by the peak inductor current and therefore the load current at which Burst Mode operation will be entered depends on the input voltage, the output voltage and the inductor value. Typical curves for Burst Mode operation entry threshold are provided in the Typical Performance Characteristics section of this data sheet. The quiescent current on V_{INBK} in Burst Mode operation is only 15 μ A. If the boost converter is enabled and V_{INBST} or V_{BST} are at a higher potential than V_{INBK} , some of the quiescent current will be supplied by the boost converter, reducing the burst quiescent current on V_{INBK} to just 9 μ A.

OPERATION

Dropout Operation

As the input voltage decreases to a value approaching the output regulation voltage, the duty cycle increases toward the maximum on-time. Further reduction of the supply voltage will force the main switch to remain on for more than one cycle until 100% duty cycle operation is reached where the main switch remains on continuously. In this dropout state, the output voltage will be determined by the input voltage less the resistive voltage drop across the main switch and series resistance of the inductor.

Slope Compensation

Current mode control requires the use of slope compensation to prevent subharmonic oscillations in the inductor current waveform at high duty cycle operation. This is accomplished internally on the LTC3100 through the addition of a compensating ramp to the current sense signal. In some current mode ICs, current limiting is performed by clamping the error amplifier voltage to a fixed maximum. This leads to a reduced output current capability at low step-down ratios. In contrast, the LTC3100 performs current limiting prior to addition of the slope compensation ramp and therefore achieves a peak inductor current limit that is independent of duty cycle.

Short-Circuit Protection

When the buck output is shorted to ground, the error amplifier will saturate high and the P-channel MOSFET switch will turn on at the start of each cycle and remain on until the current limit trips. During this minimum on-time, the inductor current will increase rapidly and will decrease very slowly during the remainder of the period due to the very small reverse voltage produced by a hard output short. To eliminate the possibility of inductor current runaway in this situation, the buck converter switching frequency is reduced to approximately 375kHz when the voltage on FBBK falls below 0.3V.

Soft-Start

The buck converter has an internal voltage mode soft-start circuit with a nominal duration of 1.3ms. The converter remains in regulation during soft-start and will therefore

respond to output load transients which occur during this time. In addition, the output voltage rise time has minimal dependency on the size of the output capacitor or load current.

Error Amplifier and Compensation

The LTC3100 buck converter utilizes an internal transconductance error amplifier. Compensation of the feedback loop is performed internally to reduce the size of the application circuit and simplify the design process. The compensation network has been designed to allow use of a wide range of output capacitors while simultaneously ensuring rapid response to load transients.

Undervoltage Lockout

If the V_{INBK} supply voltage decreases below 1.6V (typical), the buck converter will be disabled. The soft-start for the buck converter will be reset during undervoltage lockout to provide a smooth restart once the input voltage rises above the undervoltage lockout threshold.

PGOOD Comparator

The PGBK pin is an open-drain output which indicates the status of the buck converter output voltage. If the buck output voltage falls 8% below the regulation voltage, the PGBK open-drain output will pull low. The output voltage must rise 3% above the falling threshold before the pull-down will turn off. In addition, there is a 60 μ s typical deglitching delay in order to prevent false trips due to voltage transients on load steps. The PGBK output will also pull low during overtemperature shutdown and undervoltage lockout to indicate these fault conditions, or if the buck converter is disabled. The typical PGBK pull-down switch resistance is 13 Ω when $V_{INBK} = 3.3V$.

Schottky Diode

Although it is not required, adding a Schottky diode from SWBK to the ground plane will improve efficiency by about 2%.

OPERATION

LDO REGULATOR OPERATION

The LDO regulator utilizes an internal 1.3Ω (typical) P-channel MOSFET pass device to supply up to 100mA of load current with a typical dropout voltage of 130mV. The input voltage to the LDO is internally connected to the boost output (V_{BST} pin), and can share the same filter capacitor. The LDO can be operated independently of the boost (or buck) converter, providing a sufficient voltage is present on V_{BST} .

Soft-Start and Current Limit

The LDO has an independent current limit circuit that limits output current to 120mA (typical). To minimize loading on the boost converter output when enabling the LDO, the LDO current limit is soft-started over a 500 μ s period. Therefore the rise time of the LDO output voltage will depend on the amount of capacitance on the V_{LDO} pin.

Reverse Current Blocking

The LDO is designed to prevent any reverse current from V_{LDO} back to the V_{BST} pin, both in normal operation and in shutdown. If V_{LDO} is pulled above V_{BST} and V_{BST} is above 1V, there will be a small (1 μ A typical) current from V_{LDO} to ground.

COMMON FUNCTIONS

Oscillator

The 1.5MHz oscillator is shared by the boost and buck converters. It will be oscillating if either converter is enabled. If both converters are enabled, the boost N-channel MOSFET switch will be turned on coincident with the buck P-channel MOSFET switch.

MODE Control

The MODE pin is used to force fixed frequency operation ($MODE < 0.3V$) or to enable Burst Mode operation ($MODE > 0.9V$) for both the boost and buck converters. With Burst Mode operation enabled, the two converters will automatically enter or leave Burst Mode operation independently, based on their respective load conditions. There is an internal 1M Ω pull-up on MODE, in the event that the pin is left open.

Note: Leaving the pin open, or connecting it to the highest of V_{INBK} or V_{BST} , will result in the lowest Burst Mode quiescent current.

Overtemperature Shutdown

If the die temperature exceeds 150°C (typical) both converters and the LDO regulator will be disabled. All power devices will be turned off and all switch nodes will be high impedance. The soft-start circuits for both converters and the LDO are reset during overtemperature shutdown to provide a smooth recovery once the overtemperature condition is eliminated. Both converters and the LDO will restart (if enabled) when the die temperature drops to approximately 130°C.

APPLICATIONS INFORMATION

PC Board Layout Guidelines

The LTC3100 switches large currents at high frequencies. Special care should be given to the PC board layout to ensure stable, noise-free operation. You will not get advertised performance with a careless layout. Figure 1 depicts the recommended PC board layout. A large ground pin copper area will help to lower the chip temperature. A multilayer board with a separate ground plane is ideal, but not absolutely necessary.

A few key guidelines follow:

1. All circulating high current paths should be kept as short as possible. Capacitor ground connections should via down to the ground plane in the shortest route possible. The bypass capacitors on all V_{IN} and V_{OUT} pins
2. To prevent large circulating currents from disrupting the output voltage sensing, the ground for each resistor divider should be returned directly to the ground plane near the IC.
3. Use of vias in the die attach pad of the IC will enhance the thermal environment of the converter, especially if the vias extend to a ground plane region on the exposed bottom surface of the PC board.
4. Keep the connection from the resistor dividers to the feedback pins as short as possible and away from the switch pin connections.

Figure 1. Recommended Component Placement for Two-Layer PC Board

APPLICATIONS INFORMATION

COMPONENT SELECTION

Boost Output Voltage Programming

The boost output voltage is set by a resistive divider according to the following formula:

$$V_{OUT} = 1.200V \cdot \left(1 + \frac{R2}{R1}\right)$$

The external divider is connected to the output as shown in the Block Diagram. A feedforward capacitor may be placed in parallel with resistor R2 to improve the noise immunity of the feedback node, improve transient response and reduce output ripple in Burst Mode operation. A value of 33pF will generally suffice.

Boost Inductor Selection

The LTC3100 boost converter can utilize small surface mount and chip inductors due to the fast 1.5MHz switching frequency. Inductor values between 2.2μH and 4.7μH are suitable for most applications. Larger values of inductance will allow slightly greater output current capability by reducing the inductor ripple current. Increasing the inductance above 10μH will increase size while providing little improvement in output current capability.

The minimum boost inductance value is given by:

$$L > \frac{V_{IN(MIN)} \cdot (V_{OUT(MAX)} - V_{IN(MIN)})}{1.5 \cdot RIPPLE \cdot V_{OUT(MAX)}}$$

Where:

RIPPLE = Allowable Inductor Current Ripple (Amps Peak-to-Peak)

$V_{IN(MIN)}$ = Minimum Input Voltage

$V_{OUT(MAX)}$ = Maximum Output Voltage

The inductor current ripple is typically set for 20% to 40% of the maximum inductor current. High frequency ferrite core inductor materials reduce frequency dependent power losses compared to cheaper powdered iron types, improving efficiency. The inductor should have low DCR (series resistance of the winding) to reduce the I^2R power losses, and must not saturate at peak inductor current levels. Molded chokes and some chip inductors usually

do not have enough core area to support the peak inductor currents of 800mA seen on the LTC3100. To minimize radiated noise, use a shielded inductor. See Table 1 for suggested components and suppliers.

Boost Input and Output Capacitor Selection

The internal loop compensation of the LTC3100 boost converter is designed to be stable with output capacitor values of 4.7μF or greater. Low ESR (equivalent series resistance) capacitors should be used to minimize the output voltage ripple. Multilayer ceramic capacitors are an excellent choice as they have extremely low ESR and are available in small footprints. A 4.7μF to 10μF output capacitor is sufficient for most fixed frequency applications. For applications where Burst Mode operation is enabled, a minimum value of 20μF is recommended. Larger values may be used to obtain very low output ripple and to improve transient response. X5R and X7R dielectric materials are preferred for their ability to maintain capacitance over wide voltage and temperature ranges. Y5V types should not be used. Case sizes smaller than 0805 are not recommended due to their increased DC bias effect.

APPLICATIONS INFORMATION

Low ESR input capacitors reduce input switching noise and reduce the peak current drawn from the battery. It follows that ceramic capacitors are also a good choice for input decoupling and should be located as close as possible to the device. A 2.2 μ F input capacitor on the V_{INBST} pin is sufficient for most applications. Larger values may be used without limitations. For applications where the power source is more than a few inches away, a larger bulk decoupling capacitor is recommended on the input to the boost converter.

Table 2 shows a list of several ceramic capacitor manufacturers. Consult the manufacturers directly for detailed information on their selection of capacitors.

Note that even X5R and X7R type ceramic capacitors have a DC bias effect which reduces their capacitance with a DC voltage applied. This effect is particularly bad for capacitors in the smallest case sizes. Consult the manufacturer's data for the capacitor you select to be assured of having the necessary capacitance in your application.

Buck Inductor Selection

The choice of buck inductor value influences both the efficiency and the magnitude of the output voltage ripple. Larger inductance values will reduce inductor current ripple and will therefore lead to lower output voltage ripple. For a fixed DC resistance, a larger value inductor will yield higher efficiency by lowering the peak current to be closer to the average. However, a larger value inductor within the same family will generally have a greater series resistance, thereby offsetting this efficiency advantage. Given a desired peak to peak current ripple, ΔI_L , the required inductance

can be calculated via the following expression, where f represents the switching frequency in MHz:

$$L = \frac{1}{f \Delta I_L} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}} \right) (\mu H)$$

A reasonable choice for ripple current is $\Delta I_L = 100$ mA which represents 40% of the maximum 250mA load current. The DC current rating of the inductor should be at least 450mA to avoid saturation under overload or short-circuit conditions. To optimize efficiency the inductor should have a low series resistance. In particularly space restricted applications it may be advantageous to use a much smaller value inductor at the expense of larger ripple current. In such cases, the converter will operate in discontinuous conduction for a wider range of output loads and efficiency will be reduced.

In addition, there is a minimum inductor value required to maintain stability of the current loop (given the fixed internal slope compensation). Specifically, if the buck converter is going to be utilized at duty cycles over 40%, the inductance value must be at least L_{MIN} as given by the following equation:

$$L_{MIN} = 2.5 \cdot V_{OUT} (\mu H)$$

Table 3 depicts the minimum required inductance for several common output voltages.

Table 3. Buck Minimum Inductance

OUTPUT VOLTAGE	MINIMUM INDUCTANCE
0.6V	1.5 μ H
0.8V	2 μ H
1.2V	3 μ H
2V	5 μ H
2.7V	6.8 μ H
3.3V	8.3 μ H

Larger values of inductor will also provide slightly greater output current capability before reaching current limit (by reducing the peak-to-peak ripple current).

Buck Output Capacitor Selection

A low ESR output capacitor should be utilized at the buck output in order to minimize voltage ripple. Multilayer ceramic capacitors are an excellent choice as they have low ESR and are available in small footprints. In addition to controlling the output ripple magnitude, the value of the output capacitor also sets the loop crossover frequency and therefore can impact loop stability. There is both a minimum and maximum capacitance value required to ensure stability of the loop. If the output capacitance is too small, the loop crossover frequency will increase to the point where switching delay and the high frequency parasitic poles of the error amplifier will degrade the phase margin. In addition, the wider bandwidth produced by a small output capacitor will make the loop more susceptible to switching noise. At the other extreme, if the output capacitor is too large, the crossover frequency can decrease too far below the compensation zero and also lead to degraded phase margin. Table 5 provides a guideline for the range of allowable values of low ESR output capacitors. Larger value output capacitors can be accommodated provided they have sufficient ESR to stabilize the loop or by increasing

the value of the feedforward capacitor in parallel with the upper resistor divider resistor.

Note that even X5R and X7R type ceramic capacitors have a DC bias effect which reduces their capacitance with a DC voltage applied. This effect is particularly bad for capacitors in the smallest case sizes. Consult the manufacturer's data for the capacitor you select to be assured of having the necessary capacitance in your application.

Table 5. Buck Output Capacitor Range

V _{OUT}	C _{MIN}	C _{MAX}
0.6V	15μF	300μF
0.8V	15μF	230μF
1.2V	10μF	150μF
1.8V	6.8μF	90μF
2.7V	6.8μF	70μF
3.3V	6.8μF	50μF

Buck Input Capacitor Selection

The V_{INBK} pin provides current to the buck converter power switch and is also the supply pin for the buck's internal control circuitry. It is recommended that a low ESR ceramic capacitor with a value of at least 4.7μF be used to bypass this pin. The capacitor should be placed as close to the pin as possible and have a short return to ground. For applications where the power source is more than a few inches away, a larger bulk decoupling capacitor is recommended.

Buck Output Voltage Programming

The output voltage is set by a resistive divider according to the following formula:

$$V_{OUT} = 0.600V \cdot \left(1 + \frac{R_6}{R_5} \right)$$

The external divider is connected to the output as shown in the Block Diagram. It is recommended that a feedforward capacitor be placed in parallel with resistor R6 to improve the noise immunity of the feedback node and reduce output ripple in Burst Mode operation. A value of 10pF will generally suffice.

APPLICATIONS INFORMATION

LDO Output Capacitor Selection

The LDO is designed to be stable with a minimum 1 μ F output capacitor. No series resistor is required when using low ESR capacitors. For most applications, a 2.2 μ F ceramic capacitor is recommended. Larger values will improve transient response, and raise the power supply rejection ratio (PSRR) of the LDO. Refer to the Typical Performance Characteristics for the allowable range of output capacitor to ensure loop stability.

LDO Output Voltage Programming

The output voltage is set by a resistive divider according to the following formula:

$$V_{OUT} = 0.600V \cdot \left(1 + \frac{R4}{R3}\right)$$

The external divider is connected to the output as shown in the Block Diagram. For improved transient response, a feedforward capacitor may be placed in parallel with resistor R4.
