

MPQ3326B

16-Channel, 80mA/Ch, LED Driver
with Separated PWM/Analog Dimming
and I²C (Default Enable), AEC-Q100 Qualified

DESCRIPTION

The MPQ3326B is a 16-channel LED driver that can operate from a wide 4.5V to 16V input voltage (V_{IN}) range. The MPQ3326B applies 16 internal current sources in each LED string terminal. The LED current (I_{LED}) of each channel is set by an external current-setting resistor. The maximum current for each channel is 80mA.

The MPQ3326B integrates an I²C interface with up to 10 configurable I²C addresses via an external resistor. This means the MPQ3326B can support up to 10 cascaded ICs to drive the LED array. Each channel can be enabled or disabled through the I²C.

The MPQ3326B employs both separated pulse-width modulation (PWM) dimming and analog dimming for each LED channel, as well as 12-bit PWM dimming and 6-bit analog dimming for each channel. The I_{LED} ramping rate and phase shift can be configured to reduce EMI.

The MPQ3326B can output a refresh signal from the RFSH/FLT pin. The refresh signal frequency ($f_{REFRESH}$) can be set via the I²C.

Full protection features include LED open protection, LED short protection, and over-temperature protection (OTP). The device also features a fault indicator. If a protection is triggered, then the RFSH/FLT pin is pulled low, and the corresponding fault register is set.

The MPQ3326B is AECQ-100 qualified, and is available in a QFN-24 (4mmx4mm) package.

Notes:

- 1) Exceeding these ratings may damage the device.
- 2) The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance θ_{JA}, and the ambient temperature T_A. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J (MAX) - T_A) / θ_{JA}. Exceeding the maximum allowable power dissipation can generate an excessive die temperature, which may cause device to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.

- 5) Operating devices at a junction temperature up to 150°C is possible. Please contact an MPS FAE for details.
- 6) Measured on JESD51-7, 4-layer PCB. The values given in this table are only valid for comparison with other packages and cannot be used for design purposes. These values are calculated in accordance with JESD51-7, and simulated on a specified JEDEC board. They do not represent the performance obtained in an actual application. The θ_{JC} value shows the thermal resistance from the junction to case bottom.

OPERATION

The MPQ3326B applies 16 internal current sources in each LED string terminal. The LED current (I_{LED}) of all the channels is set via an external current-setting resistor, with a maximum current up to 80mA.

Enable (EN) and Star-Up

Once the input voltage (V_{IN}) exceeds its under-voltage lockout (UVLO) rising threshold ($V_{IN_UVLO_RISING}$) and the EN pin's voltage (V_{EN}) exceeds its rising threshold (V_{EN_RISING}), the system starts up.

Channel Selection

The channels can be disabled by pulling the corresponding CHxEN bit (where $x = 1, 2...16$) low.

Dimming

Each channel includes a separate 6-bit analog dimming register and 12-bit pulse-width modulation (PWM) dimming register. The MPQ3326B can support analog dimming and PWM dimming for each channel.

In analog dimming, the I_{LED} amplitude changes when the analog dimming register changes. Change the code in ICHx ($x = 1, 2...16$) to apply analog dimming for the corresponding channel. I_{LED} can be estimated with Equation (1):

$$I_{LED} = \frac{ICHx}{63} \times I_{SET} \quad (1)$$

Where ICHx is the analog dimming code for channel x (where $x = 1, 2...16$). If ICHx is set to 0, then the corresponding I_{LED} is 0A.

In PWM dimming, I_{LED} is a PWM waveform, the I_{LED} amplitude remains the same, and the I_{LED} duty varies with the PWM dimming register.

The PWM dimming duty (D_{PWM}) is set by the PWMx ($x = 1, 2...16$) register. D_{PWM} can be calculated with Equation (2):

$$D_{PWM} = \frac{PWMx}{4095} \quad (2)$$

Where PWMx is the D_{PWM} code for channel x (where $x = 1, 2...16$).

The duty changes only when the PWM duty register's 8 most significant bits (MSB) are written. If PWMx is set to 0, then the corresponding I_{LED} is 0A.

The PWM dimming frequency (f_{PWM}) can be selected via register FPWM[1:0]. Table 1 shows the FPWM[1:0] register setting for the different PWM frequencies.

Table 1: PWM Frequency Setting

FPWM[1:0]	f_{PWM}
00	220Hz
01	250Hz (default)
10	280Hz
11	330Hz

To avoid glitches during normal operation, follow the steps below:

1. Change the FPWM[1:0] value only when the EN bit is set 0.
2. Write the FPWM register, then resume writing to the other registers after a 10 μ s delay.

Phase Shift

The channel-by-channel phase-shift function is enabled by setting the PS_EN bit high.

When the phase shift function is enabled, the rising edge of each channel occurs 40 μ s after the previous channel. This means that the rising edge of the channel $x + 1$ (where $x = 1, 2...15$) I_{LED} occurs 40 μ s after the rising edge of channel x's I_{LED} .

Synchronized Output for the LCD Refresh Frequency

The fault indicator function can be enabled via the FLTEN bit.

If FLTEN = 0, the fault indicator function is disabled and the RFSH/FLT pin maintains the output refresh signal, even when a protection is triggered.

If FLTEN = 1, the fault indication function is enabled and RFSH/FLT is pulled low when a fault occurs.

Table 2 on page 14 shows RFSH/FLT’s output status.

Table 2: RFSH/FLT Pin Output Status

FLTEN	FRFSH[9:0] = 0x000 (default)		FRFSH[9:0] = 0x001 to 0x3FF	
	No Fault	Fault	No Fault	Fault
1	Pulled high externally	Low	Rectangular signal	Low
0	Pulled high externally		Rectangular signal	

The refresh signal frequency (f_{REFRESH}) is set by FRFSH[9:0]. If FRFSH[9:0] = 0x000, then RFSH/FLT outputs high. If FRFSH[9:0] = 0x001~0x3FF, then RFSH/FLT outputs a rectangular signal. f_{REFRESH} can be calculated with Equation (3):

$$f_{\text{REFRESH}} = \frac{127500}{\text{FRFSH}} \times \frac{f_{\text{PWM}}}{250} \quad (\text{Hz}) \quad (3)$$

Where FRFSH is the FRFSH[9:0] value (>0), and f_{PWM} is set by register FPWM[1:0] to 220Hz, 250Hz, 280Hz, or 330Hz.

Note that all values in Equation (5) are decimal-based and f_{REFRESH} does not change until the 8MSB are written.

If FRFSH[9:0] is written to 0x000, then the read back value is 0x1A9 to avoid a zero denominator in the internal calculation (see Equation 3).

The internal oscillator is divided by 8. As the clock refreshes the frequency generation, the FRFSH[9:0] register sets the counter number (see Figure 6).

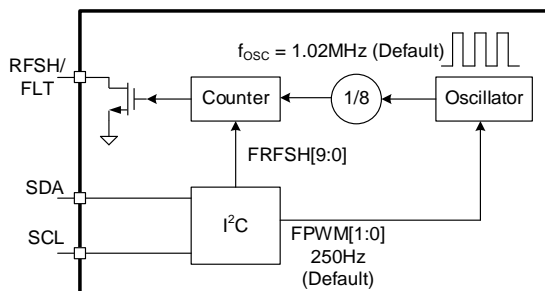

Figure 6: Refresh Frequency Generation

LED Current Slew Rate Control

To reduce EMI, change the I_{LED} rising and falling slew rate in PWM dimming. The I_{LED} rising and falling slew rate is controlled by the SLEW[1:0] register. Table 3 shows the SLEW[1:0] register settings for the different slew rates.

Table 3: Slew Rate Setting

SLEW[1:0]	Slew Rate
00	No slew rate
01	5 μ s
10	10 μ s
11	20 μ s

Protections

The MPQ3326B employs V_{IN} UVLO protection, LED short protection, LED open protection, and thermal shutdown.

The RFSH/FLT pin is an active-low, open-drain output that is pulled high to an external voltage source. If a fault occurs, the corresponding fault bit is set and RFSH/FLT is pulled low.

For LED open and short protection, hiccup mode or latch-off mode can be selected via the LATCH bit in the I²C.

If LATCH = 1, the MPQ3326B enters latch-off mode once a fault occurs. The fault channel remains off until either V_{IN} or EN turns off and resets. After the fault bit is read, FRSH/FLT is pulled high and the fault bit sets. If the fault bit is read again, then the fault bit resets.

If LATCH = 0, the MPQ3326B enters hiccup mode, during which the fault channel tries to conduct for 32 μ s every 1ms to detect whether the fault has been cleared. Once the fault is removed, FRSH/FLT is pulled high automatically and the fault bit resets when it is read.

V_{IN} Under-Voltage Lockout (UVLO) Protection

If V_{IN} drops to the V_{IN} UVLO threshold, then the IC shuts down and all the I²C registers are reset.

LED Open Protection

The LED_x (x = 1, 2...16) voltage (V_{LEDx}) drops when an LED is open. If V_{LEDx} drops below the protection threshold (about 100mV) for 4ms, then LED open protection is triggered. In this scenario, the fault channel turns off, the corresponding open fault bit (CHxO, where x = 1, 2...16) is set, and RFSH/FLT is pulled low.

LED Short Protection

If an LED short occurs, and V_{LEDx} ($x = 1, 2...16$) exceeds the voltage set by $STH[1:0]$ for 4ms, then LED short protection is triggered. The short channel turns off, the corresponding fault bit ($CHxS$, where $x = 1, 2...16$) is set, and $RFSH/FLT$ is pulled low.

The LED short protection threshold (V_{SLP}) is configured via the $STH[1:0]$ register. Table 4 shows the $STH[1:0]$ register setting for different LED short protection thresholds.

Table 4: LED Short Protection Threshold Setting

STH[1:0]	V_{SLP}
00	2V
01	3V
10	4V
11	5V

Over-Temperature Protection (OTP)

If the IC temperature exceeds 170°C, then over-temperature protection (OTP) is triggered, all channels turn off, $RFSH/FLT$ is pulled low, and FT_OTP is set. Once the temperature drops to about 150°C, all channels turn on again and the IC resumes normal operation.

I²C INTERFACE

I²C Chip Address

The device address is 0x30~0x39, which can be configured via the ADDR resistor (R_{ADDR}). The internal current source flows to R_{ADDR} , and the ADDR voltage (V_{ADDR}) determines the I²C address. Ten different addresses can be configured via R_{ADDR} .

Table 5 shows the various resistor ratio (R_{ADDR} / R_{RSET}) configurations to set the I²C address.

Table 5: I2C Address Setting

R_{ADDR}, R_{RSET}	I ² C Address (A3, A2, A1, A0)
<0.05	0000
>0.05, <0.15	0001
>0.15, <0.25	0010
>0.25, <0.35	0011
>0.35, <0.45	0100
>0.45, <0.55	0101
>0.55, <0.65	0110
>0.65, <0.75	0111
>0.75, <0.85	1000
>0.85, <0.95	1001

At start-up, the IC checks the I²C address first. This address remains the same during operation until the IC's power is reset.

After a start (S) condition, the I²C-compatible master sends a 7-bit address, followed by an eighth data direction bit (where 1 = read and 0 = write). The eighth bit indicates the register address to/from which the data is written/read (see Figure 7).

Figure 7: The I²C-Compatible Device Address

To avoid glitches during normal operation, follow the steps below:

1. Change the FPWM[1:0] value only when the EN bit is set to 0.
2. Write the FPWM[1:0] register, then resume writing to the other registers after a 10 μ s delay.

APPLICATION INFORMATION

Setting the LED Current

Connect a resistor from the ISET pin to GND to set I_{LED} for all 16 channels. I_{LED} can be calculated with Equation (4):

$$I_{LED} (mA) = \frac{1200}{R_{ISET} (k\Omega)} \quad (4)$$

PCB Layout Guidelines

Efficient PCB layout is critical for stable operation. For the best results, refer to Figure 8 and following the guidelines below:

1. Place the VIN capacitor close to the VIN pin.
2. Add multiple vias to the capacitor's GND.
3. Ensure that the traces from the LED anode to the LEDx pins are wide enough to support the set current (up to 80mA).
